What Is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides resizable computing capacity in the Amazon Web Services (AWS) cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. Amazon EC2 enables you to scale up or down to handle changes in requirements or spikes in popularity, reducing your need to forecast traffic.

Features of Amazon EC2

Amazon EC2 provides the following features:

- Virtual computing environments, known as instances
- Pre-configured templates for your instances, known as Amazon Machine Images (AMIs), that package the bits you need for your server (including the operating system and additional software)
- Various configurations of CPU, memory, storage, and networking capacity for your instances, known as instance types
- Secure login information for your instances using key pairs (AWS stores the public key, and you store the private key in a secure place)
- Storage volumes for temporary data that’s deleted when you stop or terminate your instance, known as instance store volumes
- Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS), known as Amazon EBS volumes
- Multiple physical locations for your resources, such as instances and Amazon EBS volumes, known as regions and Availability Zones
- A firewall that enables you to specify the protocols, ports, and source IP ranges that can reach your instances using security groups
- Static IP addresses for dynamic cloud computing, known as Elastic IP addresses
- Metadata, known as tags, that you can create and assign to your Amazon EC2 resources
- Virtual networks you can create that are logically isolated from the rest of the AWS cloud, and that you can optionally connect to your own network, known as virtual private clouds (VPCs)

For more information about the features of Amazon EC2, see the Amazon EC2 product page.
How to Get Started with Amazon EC2

The first thing you need to do is get set up to use Amazon EC2. After you are set up, you are ready to complete the Getting Started tutorial for Amazon EC2. Whenever you need more information about a feature of Amazon EC2, you can read the technical documentation.

Getting Started

- Setting Up with Amazon EC2 (p. 19)
- Getting Started with Amazon EC2 Linux Instances (p. 24)
- Getting Started with Amazon EC2 Windows Instances

Basics

- Instances and AMIs (p. 4)
- Instance Types (p. 97)
- Regions and Availability Zones (p. 7)
- Tags (p. 610)

Networking and Security

- Amazon EC2 Key Pairs (p. 433)
- Security Groups (p. 440)
- Elastic IP Addresses (EIP) (p. 498)
- Amazon EC2 and Amazon VPC (p. 485)

Storage

- Amazon EBS (p. 523)
- Instance Store (p. 582)

If you have questions about whether AWS is right for you, Contact AWS Sales. If you have technical questions about Amazon EC2, use the Amazon EC2 forum.

Related Services

You can provision Amazon EC2 resources, such as instances and volumes, directly using Amazon EC2. You can also provision Amazon EC2 resources using other services in AWS. For more information, see the following documentation:

- Auto Scaling Developer Guide
- AWS CloudFormation User Guide
- AWS Elastic Beanstalk Developer Guide
- AWS OpsWorks User Guide
To automatically distribute incoming application traffic across multiple instances, use Elastic Load Balancing. For more information, see Elastic Load Balancing Developer Guide.

To monitor basic statistics for your instances and Amazon EBS volumes, use Amazon CloudWatch. For more information, see Monitoring Your Instances with CloudWatch (p. 364).

To monitor the calls made to the Amazon EC2 API for your account, including calls made by the AWS Management Console, command line tools, and other services, use AWS CloudTrail. For more information, see the AWS CloudTrail User Guide.

To get a managed relational database in the cloud, use Amazon Relational Database Service (Amazon RDS) to launch a database instance. Although you can set up a database on an EC2 instance, Amazon RDS offers the advantage of handling your database management tasks, such as patching the software, backing up, and storing the backups. For more information, see Amazon Relational Database Service Developer Guide.

Accessing Amazon EC2

Amazon EC2 provides a web-based user interface, the Amazon EC2 console. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting EC2 from the console home page.

If you prefer to use a command line interface, you have several options:

- **AWS Command Line Interface (CLI)**: Provides commands for a broad set of AWS products, and is supported on Windows, Mac, and Linux/Unix. To get started, see AWS Command Line Interface User Guide. For more information about the commands for Amazon EC2, see ec2.

- **Amazon EC2 Command Line Interface (CLI) Tools**: Provides commands for Amazon EC2, Amazon EBS, and Amazon VPC, and is supported on Windows, Mac, and Linux/Unix. To get started, see Setting Up the Amazon EC2 Command Line Interface Tools on Linux and Commands (CLI Tools) in the Amazon Elastic Compute Cloud Command Line Reference.

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named Action. For more information about the API actions for Amazon EC2, see Actions in the Amazon Elastic Compute Cloud API Reference.

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automatically take care of tasks such as cryptographically signing your requests, retrying requests, and handling error responses, so that it is easier for you to get started. For more information about downloading the AWS SDKs, see AWS SDKs and Tools. For a list of available APIs for Amazon EC2, see Available APIs for Amazon EC2 (p. 664).

Pricing for Amazon EC2

When you sign up for AWS, you can get started with Amazon EC2 for free using the AWS Free Usage Tier.

Amazon EC2 provides the following purchasing options for instances:
On-Demand Instances
Pay for the instances that you use by the hour, with no long-term commitments or upfront payments.

Reserved Instances
Make a low, one-time, upfront payment for an instance, reserve it for a one- or three-year term, and pay a significantly lower hourly rate for these instances.

Spot Instances
Specify the maximum hourly price that you are willing to pay to run a particular instance type. The Spot Price fluctuates based on supply and demand, but you never pay more than the maximum price you specified. If the Spot Price moves higher than your maximum price, Amazon EC2 shuts down your Spot Instances.

For a complete list of charges and specific prices for Amazon EC2, see Amazon EC2 Pricing.

To calculate the cost of a sample provisioned environment, see AWS Economics Center.

To see your bill, go to your AWS Account Activity page. Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see AWS Account Billing.

If you have questions concerning AWS billing, accounts, and events, Contact AWS Support.

For an overview of Trusted Advisor, a service that helps you optimize the costs, security, and performance of your AWS environment, see AWS Trusted Advisor.

Instances and AMIs

An Amazon Machine Image (AMI) is a template that contains a software configuration (for example, an operating system, an application server, and applications). From an AMI, you launch an instance, which is a copy of the AMI running as a virtual server in the cloud. You can launch multiple instances of an AMI, as shown in the following figure.

![Instance Diagram](image)

Your instances keep running until you stop or terminate them, or until they fail. If an instance fails, you can launch a new one from the AMI.

Instances

You can launch different types of instances from a single AMI. An instance type essentially determines the hardware of the host computer used for your instance. Each instance type offers different compute and memory capabilities. Select an instance type based on the amount of memory and computing power...
that you need for the application or software that you plan to run on the instance. For more information about the hardware specifications for each Amazon EC2 instance type, see Instance Type Details.

After you launch an instance, it looks like a traditional host, and you can interact with it as you would any computer. You have complete control of your instances; you can use sudo to run commands that require root privileges.

Your AWS account has a limit on the number of instances that you can have running. For more information about this limit, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.

In addition to the limit on running instances, there is a limit on the overall number of instances that you can have (whether running, stopped, or in any other state except for terminated). This overall instance limit is two times your running instance limit.

Storage for Your Instance

The root device for your instance contains the image used to boot the instance. For more information, see Amazon EC2 Root Device Volume (p. 13).

Your instance may include local storage volumes, known as instance store volumes, which you can configure at launch time with block device mapping. For more information, see Block Device Mapping (p. 592). After these volumes have been added to and mapped on your instance, they are available for you to mount and use. If your instance fails, or if your instance is stopped or terminated, the data on these volumes is lost; therefore, these volumes are best used for temporary data. For important data, you should use a replication strategy across multiple instances in order to keep your data safe, or store your persistent data in Amazon S3 or Amazon EBS volumes. For more information, see Storage (p. 521).

Security Best Practices

• Use AWS Identity and Access Management (IAM) to control access to your AWS resources, including your instances. You can create IAM users and groups under your AWS account, assign security credentials to each, and control the access that each has to resources and services in AWS. For more information, see Controlling Access to Amazon EC2 Resources (p. 448).

• Restrict access by only allowing trusted hosts or networks to access ports on your instance. For example, you can restrict SSH access by restricting incoming traffic on port 22. For more information, see Amazon EC2 Security Groups (p. 440).

• Review the rules in your security groups regularly, and ensure that you apply the principle of least privilege—only open up permissions that you require. You can also create different security groups to deal with instances that have different security requirements. Consider creating a bastion security group that allows external logins, and keep the remainder of your instances in a group that does not allow external logins.

• Disable password-based logins for instances launched from your AMI. Passwords can be found or cracked, and are a security risk. For more information, see Disable Password-Based Logins for Root (p. 61). For more information about sharing AMIs safely, see Shared AMIs (p. 54).

Stopping, Starting, and Terminating Instances

Stopping an instance

When an instance is stopped, the instance performs a normal shutdown, and then transitions to a stopped state. All of its Amazon EBS volumes remain attached, and you can start the instance again at a later time.

You are not charged for additional instance hours while the instance is in a stopped state. A full instance hour will be charged for every transition from a stopped state to a running state, even if this happens
multiple times within a single hour. If the instance type was changed while the instance was stopped, you will be charged the rate for the new instance type after the instance is started. All of the associated Amazon EBS usage of your instance, including root device usage, is billed using typical Amazon EBS prices.

When an instance is in a stopped state, you can attach or detach Amazon EBS volumes. You can also create an AMI from the instance, and you can change the kernel, RAM disk, and instance type.

Terminating an instance

When an instance is terminated, the instance performs a normal shutdown, then the attached Amazon EBS volumes are deleted unless the volume's `deleteOnTermination` attribute is set to `false`. The instance itself is also deleted, and you can't start the instance again at a later time.

To prevent accidental termination, you can disable instance termination. If you do so, ensure that the `disableApiTermination` attribute is set to `true` for the instance. To control the behavior of an instance shutdown, such as `shutdown -h` in Linux or `shutdown` in Windows, set the `instanceInitiatedShutdownBehavior` instance attribute to `stop` or `terminate` as desired. Instances with Amazon EBS volumes for the root device default to `stop`, and instances with instance-store root devices are always terminated as the result of an instance shutdown.

For more information, see Instance Lifecycle (p. 297).

AMIs

Amazon Web Services (AWS) publishes many Amazon Machine Images (AMIs) that contain common software configurations for public use. In addition, members of the AWS developer community have published their own custom AMIs. You can also create your own custom AMI or AMIs; doing so enables you to quickly and easily start new instances that have everything you need. For example, if your application is a website or a web service, your AMI could include a web server, the associated static content, and the code for the dynamic pages. As a result, after you launch an instance from this AMI, your web server starts, and your application is ready to accept requests.

All AMIs are categorized as either `backed by Amazon EBS`, which means that the root device for an instance launched from the AMI is an Amazon EBS volume, or `backed by instance store`, which means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

The description of an AMI indicates the type of root device (either `ebs` or `instance store`). This is important because there are significant differences in what you can do with each type of AMI. For more information about these differences, see Storage for the Root Device (p. 50).
Regions and Availability Zones

Amazon EC2 is hosted in multiple locations world-wide. These locations are composed of regions and Availability Zones. Each region is a separate geographic area. Each region has multiple, isolated locations known as Availability Zones. Amazon EC2 provides you the ability to place resources, such as instances, and data in multiple locations. Resources aren't replicated across regions unless you do so specifically.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of instances that are in the same location. If you host all your instances in a single location that is affected by such a failure, none of your instances would be available.

**Note**

Some AWS resources might not be available in all regions and Availability Zones. Ensure that you can create the resources you need in the desired regions or Availability Zone before deploying your applications.

**Topics**

- Region and Availability Zone Concepts (p. 7)
- Describing Your Regions and Availability Zones (p. 9)
- Specifying the Region for a Resource (p. 11)
- Launching Instances in an Availability Zone (p. 12)
- Migrating an Instance to Another Availability Zone (p. 13)

### Region and Availability Zone Concepts

Each region is completely independent. Each Availability Zone is isolated, but the Availability Zones in a region are connected through low-latency links. The following diagram illustrates the relationship between regions and Availability Zones.

![Diagram of Regions and Availability Zones](image)

Amazon EC2 resources are either global, tied to a region, or tied to an Availability Zone. For more information, see Resource Locations (p. 606).

### Regions

Each Amazon EC2 region is designed to be completely isolated from the other Amazon EC2 regions. This achieves the greatest possible fault tolerance and stability.

Amazon EC2 provides multiple regions so that you can launch Amazon EC2 instances in locations that meet your requirements. For example, you might want to launch instances in Europe to be closer to your European customers or to meet legal requirements. The following table lists the regions that provide support for Amazon EC2.
When you view your resources, you’ll only see the resources tied to the region you’ve specified. This is because regions are isolated from each other, and we don’t replicate resources across regions automatically.

When you work with an instance using the command line interface or API actions, you must specify its regional endpoint. For more information about the regions and endpoints for Amazon EC2, see Regions and Endpoints in the Amazon Web Services General Reference. For more information about endpoints and protocols in AWS GovCloud (US), see AWS GovCloud (US) Endpoints in the AWS GovCloud (US) User Guide.

When you launch an instance, you must select an AMI that’s in the same region. If the AMI is in another region, you can copy the AMI to the region you’re using. For more information, see Copying an AMI (p. 80).

All communications between regions is across the public Internet. Therefore, you should use the appropriate encryption methods to protect your data. Data transfer between regions is charged at the Internet data transfer rate for both the sending and the receiving instance. For more information, see Amazon EC2 Pricing - Data Transfer.

### Availability Zones

You can list the Availability Zones that are available to your account. For more information, see Describing Your Regions and Availability Zones (p. 9).

When you launch an instance, you can select an Availability Zone or let us choose one for you. If you distribute your instances across multiple Availability Zones and one instance fails, you can design your application so that an instance in another Availability Zone can handle requests.

You can also use Elastic IP addresses to mask the failure of an instance in one Availability Zone by rapidly remapping the address to an instance in another Availability Zone. For more information, see Elastic IP Addresses (EIP) (p. 498).

To ensure that resources are distributed across the Availability Zones for a region, we independently map Availability Zones to identifiers for each account. For example, your Availability Zone `us-east-1a` might not be the same location as `us-east-1a` for another account. Note that there’s no way for you to coordinate Availability Zones between accounts.

As Availability Zones grow over time, our ability to expand them can become constrained. If this happens, we might restrict you from launching an instance in a constrained Availability Zone unless you already have an instance in that Availability Zone. Eventually, we might also remove the constrained Availability Zone from the list of Availability Zones for new customers. Therefore, your account might have a different number of available Availability Zones in a region than another account.
Describing Your Regions and Availability Zones

You can use the AWS Management Console or the command line interface to determine which regions and Availability Zones are available for your use. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

To find your regions and Availability Zones using the AWS Management Console

1. Open the AWS Management Console.
2. From the navigation bar, view the options in the region selector.

3. Open the Amazon EC2 console. Your Availability Zones are listed on the dashboard under Service Health, under Availability Zone Status.

Service Health

Service Status:

✔ US East (N. Virginia):
This service is operating normally

Availability Zone Status:

✔ us-east-1b:
Availability zone is operating normally

✔ us-east-1c:
Availability zone is operating normally

✔ us-east-1d:
Availability zone is operating normally
To find your regions and Availability Zones using the AWS CLI

1. Use the `describe-regions` command as follows to describe your regions.

```
PROMPT> aws ec2 describe-regions
{
  "Regions": [
    {
      "Endpoint": "ec2.us-east-1.amazonaws.com",
      "RegionName": "us-east-1"
    },
    {
      "Endpoint": "ec2.ap-southeast-1.amazonaws.com",
      "RegionName": "ap-southeast-1"
    },
    {
      "Endpoint": "ec2.ap-southeast-2.amazonaws.com",
      "RegionName": "ap-southeast-2"
    },
    ...
  ]
}
```

2. Use the `describe-availability-zones` command as follows to describe your Availability Zones within the `us-east-1` region.

```
PROMPT> aws ec2 describe-availability-zones --region us-east-1
{
  "AvailabilityZones": [
    {
      "State": "available",
      "RegionName": "us-east-1",
      "Messages": [],
      "ZoneName": "us-east-1b"
    },
    {
      "State": "available",
      "RegionName": "us-east-1",
      "Messages": [],
      "ZoneName": "us-east-1c"
    },
    {
      "State": "available",
      "RegionName": "us-east-1",
      "Messages": [],
      "ZoneName": "us-east-1d"
    }
  ]
}
```

To find your regions and Availability Zones using the Amazon EC2 CLI

1. Use the `ec2-describe-regions` command as follows to describe your regions.
2. Use the `ec2-describe-availability-zones` command as follows to describe your Availability Zones within the `us-east-1` region.

```
PROMPT> ec2-describe-availability-zones --region us-east-1
AVAILABILITYZONE us-east-1a available us-east-1
AVAILABILITYZONE us-east-1b available us-east-1
AVAILABILITYZONE us-east-1c available us-east-1
AVAILABILITYZONE us-east-1d available us-east-1
```

### Specifying the Region for a Resource

Every time you create an Amazon EC2 resource, you can specify the region for the resource. You can specify the region for a resource using the AWS Management Console or the command line.

**To specify the region for a resource using the console**

1. Open the Amazon EC2 console.
2. Use the region selector in the navigation bar.

```
[US East (N. Virginia)]
   US West (Oregon)
   US West (N. California)
   EU (Ireland)
   Asia Pacific (Singapore)
   Asia Pacific (Tokyo)
   Asia Pacific (Sydney)
   South America (São Paulo)
```

**To specify the default region using the command line**

You can set the value of an environment variable to the desired regional endpoint (for example, `https://ec2.us-west-1.amazonaws.com`):
• AWS_DEFAULT_REGION (AWS CLI)
• EC2_URL (Amazon EC2 CLI)

Alternatively, you can use the --region command line option with each individual command. For example, --region us-west-1.

For more information about the endpoints for Amazon EC2, see Amazon Elastic Compute Cloud Endpoints.

**Launching Instances in an Availability Zone**

When you launch an instance, select a region that puts your instances closer to specific customers, or meets the legal or other requirements you have. By launching your instances in separate Availability Zones, you can protect your applications from the failure of a single location.

When you launch an instance, you can optionally specify an Availability Zone in the region that you are using. If you do not specify an Availability Zone, we select one for you. When you launch your initial instances, we recommend that you accept the default Availability Zone, because this enables us to select the best Availability Zone for you based on system health and available capacity. If you launch additional instances, only specify an Availability Zone if your new instances must be close to, or separated from, your running instances.

**To specify an Availability Zone for your instance using the console**

1. Open the Amazon EC2 console.
2. On the dashboard, click Launch Instance.
3. Follow the directions for the wizard. On the Configure Instance Details page, do the following:
   - [EC2-Classic] Select one of the Availability Zone options from the list, or select No Preference to enable us to select the best one for you.
   - [EC2-VPC] Select one of the subnet options from the list, or select No preference (default subnet in any Availability Zone) to enable us to select the best one for you.

**To specify an Availability Zone for your instance using the AWS CLI**

You can use the run-instances command with one of the following options:

- [EC2-Classic] --placement
- [EC2-VPC] --subnet-id

**To specify an Availability Zone for your instance using the Amazon EC2 CLI**

You can use the ec2-run-instances command with one of the following options:

- [EC2-Classic] --availability-zone
- [EC2-VPC] --subnet
Migrating an Instance to Another Availability Zone

If you need to, you can migrate an instance from one Availability Zone to another. For example, if you are trying to modify the instance type of your instance and we can't launch an instance of the new instance type in the current Availability Zone, you could migrate the instance to an Availability Zone where we can launch an instance of that instance type.

The migration process involves creating an AMI from the original instance, launching an instance in the new Availability Zone, and updating the configuration of the new instance, as shown in the following procedure.

To migrate an instance to another Availability Zone

1. Create an AMI from the instance. The procedure depends on the operating system and the type of root device volume for the instance. For more information, see the documentation that corresponds to your operating system and root device volume:
   - Creating an Amazon EBS-Backed Linux AMI (p. 69)
   - Creating an Instance Store-Backed Linux AMI (p. 72)
   - Creating an Amazon EBS-Backed Windows AMI
   - Creating an Instance Store-Backed Windows AMI

2. [EC2-VPC] If you need to preserve the private IP address of the instance, you must delete the subnet in the current Availability Zone and then create a subnet in the new Availability Zone with the same IP address range as the original subnet. Note that you must terminate all instances in a subnet before you can delete it. Therefore, you should move all instances in the current subnet to the new subnet.

3. Launch an instance from the AMI that you just created, specifying the new Availability Zone or subnet. You can use the same instance type as the original instance, or select a new instance type. For more information, see Launching Instances in an Availability Zone (p. 12).

4. If the original instance has an associated Elastic IP address, associate it with the new instance. For more information, see Associating an Elastic IP Address with a Different Running Instance (p. 502).

5. If the original instance is a Reserved Instance, change the Availability Zone for your reservation. (If you also changed the instance type, you can also change the instance type for your reservation.) For more information, see Submitting Modification Requests (p. 236).

6. (Optional) Terminate the original instance. For more information, see Terminating an Instance (p. 325).

Amazon EC2 Root Device Volume

When you launch an instance, the root device volume contains the image used to boot the instance. When we introduced Amazon EC2, all AMIs were backed by Amazon EC2 instance store, which means the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3. After we introduced Amazon EBS, we introduced AMIs that are backed by Amazon EBS. This means that the root device for an instance launched from the AMI is an Amazon EBS volume created from an Amazon EBS snapshot. You can choose between AMIs based by Amazon EC2 instance store and AMIs backed by Amazon EBS. We recommend that you use AMIs backed by Amazon EBS, because they launch faster and use persistent storage.

Root Device Storage Concepts

You can launch an instance from one of two types of AMIs: an instance store-backed AMI or an Amazon EBS-backed AMI. The description of an AMI includes which type of AMI it is; you’ll see the root device referred to in some places as either ebs (for Amazon EBS-backed) or instance store (for instance store-backed). This is important because there are significant differences between what you can do with each type of AMI. For more information about these differences, see Storage for the Root Device (p. 50).

Instance Store-backed Instances

Instances that use instance stores for the root device automatically have instance store volumes available, with one serving as the root device volume. When an instance is launched, the image that is used to boot the instance is copied to the root volume (typically sda1). Any data on the instance store volumes persists as long as the instance is running, but this data is deleted when the instance is terminated (instance store-backed instances do not support the Stop action) or if it fails (such as if an underlying drive has issues).

After an instance store-backed instance fails or terminates, it cannot be restored. If you plan to use Amazon EC2 instance store-backed instances, we highly recommend that you distribute the data on your instance stores across multiple Availability Zones. You should also back up the data on your instance store volumes to persistent storage on a regular basis.

For more information, see Amazon EC2 Instance Store (p. 582).

Amazon EBS-backed Instances

Instances that use Amazon EBS for the root device automatically have an Amazon EBS volume attached. When you launch an Amazon EBS-backed instance, we create an Amazon EBS volume for each Amazon EBS snapshot referenced by the AMI you use. You can optionally use other Amazon EBS volumes or instance store volumes.
An Amazon EBS-backed instance can be stopped and later restarted without affecting data stored in the attached volumes. There are various instance- and volume-related tasks you can do when an Amazon EBS-backed instance is in a stopped state. For example, you can modify the properties of the instance, you can change the size of your instance or update the kernel it is using, or you can attach your root volume to a different running instance for debugging or any other purpose.

By default, the root device volume and the other Amazon EBS volumes attached when you launch an Amazon EBS-backed instance are automatically deleted when the instance terminates. For information about how to change this behavior when you launch an instance, see Changing the Root Device Volume to Persist (p. 16).

By default, any Amazon EBS volumes that you attach to a running instance are detached with their data intact when the instance terminates. You can attach a detached volume to any running instance.

If an Amazon EBS-backed instance fails, you can restore your session by following one of these methods:

- Stop and then start again.
- Automatically snapshot all relevant volumes and create a new AMI. For more information, see Creating an Amazon EBS-Backed Linux AMI (p. 69).
- Attach the volume to the new instance by following these steps:
  1. Create a snapshot of the root volume.
  2. Register a new AMI using the snapshot.
  3. Launch a new instance from the new AMI.
  4. Detach the remaining Amazon EBS volumes from the old instance.
  5. Reattach the Amazon EBS volumes to the new instance.

We recommend using either the first or the second method for failed instances with normal volume size, and the third method for failed instances with large volumes.

Choosing an AMI by Root Device Type

The AMI that you specify when you launch your instance determines the type of root device volume that your instance has.

**To choose an Amazon EBS-backed AMI using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. From the filter lists, select the image type (such as Public images), the operating system (such as Amazon Linux), and EBS images.
4. (Optional) To get additional information to help you make your choice, click the Show/Hide Columns icon, update the columns to display, and click Close.
5. Choose an AMI and write down its AMI ID.

**To choose an instance store-backed AMI using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. From the filter lists, select the image type (such as Public images), the operating system (such as Amazon Linux), and Instance store images.
4. (Optional) To get additional information to help you make your choice, click the Show/Hide Columns icon, update the columns to display, and click Close.
5. Choose an AMI and write down its AMI ID.

To verify the type of the root device volume of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-images` (AWS CLI)
- `ec2-describe-images` (Amazon EC2 CLI)
- `Get-EC2Image` (AWS Tools for Windows PowerShell)

**Determining the Root Device Type of Your Instance**

**To determine the root device type of an instance using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, click **Instances**, and select the instance.
3. Check the value of **Root device type** in the **Description** tab as follows:
   - If the value is **ebs**, this is an Amazon EBS-backed instance.
   - If the value is **instance store**, this is an instance store-backed instance.

**To determine the root device type of an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-instances` (AWS CLI)
- `ec2-describe-instances` (Amazon EC2 CLI)
- `Get-EC2Instance` (AWS Tools for Windows PowerShell)

**Changing the Root Device Volume to Persist**

By default, the root device volume for an AMI backed by Amazon EBS is deleted when the instance terminates. To change the default behavior, set the `DeleteOnTermination` attribute to `false` using a block device mapping.

**Changing the Root Volume to Persist Using the Console**

Using the console, you can change the `DeleteOnTermination` attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

**To change the root device volume of an instance to persist at launch using the console**

1. Open the Amazon EC2 console.
2. From the Amazon EC2 console dashboard, click **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose the AMI to use and click **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, deselect the **Delete On Termination** check box for the root volume.
6. Complete the remaining wizard pages, and then click **Launch**.

You can verify the setting by viewing details for the root device volume on the instance’s details pane. Next to **Block devices**, click the entry for the root device volume. By default, **Delete on termination** is True. If you change the default behavior, **Delete on termination** is False.

**Changing the Root Volume of an Instance to Persist Using the AWS CLI**

Using the AWS CLI, you can change the `DeleteOnTermination` attribute when you launch an instance or while the instance is running. The root device is typically `/dev/sda1` (Linux) or `xvda` (Windows).

**Example at Launch**

Use the `run-instances` command to preserve the root volume by including a block device mapping that sets its `DeleteOnTermination` attribute for to false.

```
aws ec2 run-instances --image-id ami-1a2b3c4d --block-device-mappings "[{"DeviceName": "/dev/sda1", "Ebs": {"DeleteOnTermination": false}}]"
```

You can confirm that `DeleteOnTermination` is false by using the `describe-instances` command and looking for the `BlockDeviceMappings` entry for `/dev/sda1` in the command output, as shown here.

```
...
"BlockDeviceMappings": [ 
   
   "DeviceName": "/dev/sda1",
   "Ebs": { 
      "Status": "attached",
      "DeleteOnTermination": false,
      "VolumeId": "vol-877166c8",
      "AttachTime": "2013-07-19T02:42:39.000Z"
   } 
] 
...
```

**Example While the Instance is Running**

Use the `modify-instance-attribute` command to preserve the root volume by including a block device mapping that sets its `DeleteOnTermination` attribute to false.

```
aws ec2 modify-instance-attribute --instance-id i-5203422c --block-device-mappings "[{"DeviceName": "/dev/sda1", "Ebs": {"DeleteOnTermination": false}}]"
```

**Changing the Root Volume of an Instance to Persist Using the Amazon EC2 CLI**

Using the Amazon EC2 CLI, you can change the `DeleteOnTermination` attribute when you launch an instance or while the instance is running. The root device is typically `/dev/sda1` (Linux) or `xvda` (Windows).
Example at Launch

Use the `ec2-run-instances` command to include a block device mapping that sets the `DeleteOnTermination` flag for the root device to `false`. Include the `-v` option to run the command in verbose mode.

```
ec2-run-instances ami-1a2b3c4d -b /dev/sda1=:false other parameters... -v
```

If you're using the command line tools on a Windows system, you must put quotation marks around the block device mapping value.

```
ec2-run-instances ami-1a2b3c4d -b "xvda=:false" other parameters... -v
```

By running the command in verbose mode, you can see the underlying request and response, and confirm that `DeleteOnTermination` is `false`, as shown here.

```
...<blockDeviceMapping>
  <item>
    <deviceName>/dev/sda1</deviceName>
    <ebs>
      <deleteOnTermination>false</deleteOnTermination>
    </ebs>
  </item>
</blockDeviceMapping>...
```

Example While the Instance is Running

Use the `ec2-modify-instance-attribute` command to preserve the root volume by setting its `DeleteOnTermination` attribute to `false`.

```
ec2-modify-instance-attribute i-5203422c -b /dev/sda1=:false
```

If you're using the command line tools on a Windows system, you must put quotation marks around the block device mapping value.

```
ec2-modify-instance-attribute i-5203422c -b "xvda=:false"
```
Setting Up with Amazon EC2

Before you use Amazon EC2 for the first time, complete the following tasks:

1. Sign Up for AWS (p. 19)
2. Create an IAM User (p. 19)
3. Create a Key Pair (p. 21)
4. Create a Security Group (p. 22)

Sign Up for AWS

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including Amazon EC2. You are charged only for the services that you use.

With Amazon EC2, you pay only for what you use. If you are a new AWS customer, you can get started with Amazon EC2 for free. For more information, see AWS Free Usage Tier.

If you have an AWS account already, skip to the next task. If you don't have an AWS account, use the following procedure to create one.

To create an AWS account

2. Follow the on-screen instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a PIN using the phone keypad.

   Note your AWS account number, because you'll need it for the next task.

Create an IAM User

Services in AWS, such as Amazon EC2, require that you provide credentials when you access them, so that the service can determine whether you have permission to access its resources. The console requires your password. You can create access keys for your AWS account to access the command line interface
or API. However, we don't recommend that you access AWS using the credentials for your AWS account; we recommend that you use AWS Identity and Access Management (IAM) instead. Create an IAM user, and then add the user to an IAM group with administrative permissions or and grant this user administrative permissions. You can then access AWS using a special URL and the credentials for the IAM user.

If you signed up for AWS but have not created an IAM user for yourself, you can create one using the IAM console.

**To create an administrator group with an IAM user**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
   Enter the email address and password that you used when you signed up for AWS.
2. From the dashboard, click **Create a New Group of Users**.
3. Enter **Administrators** in the **Group Name** box.
4. Select the **Administrator Access** policy template, which grants users in the group permission to perform any action on any AWS resource, and then click **Continue**.
5. On the **Create New Users** tab, enter an IAM user name for yourself in box 1, and then click **Continue**.
6. When prompted, click **Continue**.
7. If you plan to use the CLI or the API for Amazon EC2, click **Download Credentials** or **Show User Security Credentials**, and then save the access keys in a secure place. When you have finished, click **Close Window**. Note that you can't get the secret access key after you close this window.
8. If you plan to use the AWS Management Console, click **Users** in the navigation pane, and then follow these steps:
   a. Select the user you just created.
   b. Click the **Security Credentials** tab in the details pane.
   c. Under **Sign-In Credentials**, click **Manage Password**.
   d. In the **Manage Password** dialog box, select an option and click **Apply**.
   e. If you assigned an auto-generated password, click **Download Credentials** or **Show User Security Credentials** and save the password in a secure place.

To sign in as this new IAM user, sign out of the AWS console, then use the following URL, where *your_aws_account_id* is your AWS account number without the hyphens (for example, if your AWS account number is 1234-5678-9012, your AWS account ID is 123456789012):

https://your_aws_account_id.signin.aws.amazon.com/console/

Enter the IAM user name and password that you just created. When you're signed in, the navigation bar displays "*your_user_name* @ *your_aws_account_id*".

If you don't want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, click **Create Account Alias** and enter an alias, such as your company name. To sign in after you create an account alias, use the following URL:

https://your_account_alias.signin.aws.amazon.com/console/

To verify the sign-in link for IAM users for your account, open the IAM console and check under **AWS Account Alias** on the dashboard.

For more information about IAM, see **IAM and Amazon EC2** (p. 448).
Create a Key Pair

AWS uses public-key cryptography to secure the login information for your instance. A Linux instance has no password; you use a key pair to log in to your instance securely. You specify the name of the key pair when you launch your instance, then provide the private key when you log in.

If you haven't created a key pair already, you can create one using the Amazon EC2 console. Note that if you plan to launch instances in multiple regions, you'll need to create a key pair in each region. For more information about regions, see Regions and Availability Zones (p. 7).

To create a key pair

1. Open the Amazon EC2 console.
2. From the navigation bar, select a region for the key pair. You can select any region that's available to you, regardless of your location. However, key pairs are specific to a region; for example, if you plan to launch an instance in the US West (Oregon) Region, you must create a key pair for the instance in the US West (Oregon) Region.
3. Click Key Pairs in the navigation pane.
4. Click Create Key Pair.
5. Enter a name for the new key pair in the Key pair name field of the Create Key Pair dialog box, and then click Create. Choose a name that is easy for you to remember, such as your IAM user name, followed by -key-pair, plus the region name. For example, me-key-pair-uswest2.
6. The private key file is automatically downloaded by your browser. The base file name is the name you specified as the name of your key pair, and the file name extension is .pem. Save the private key file in a safe place.

   **Important**
   This is the only chance for you to save the private key file. You'll need to provide the name of your key pair when you launch an instance and the corresponding private key each time you connect to the instance.

7. If you will use an SSH client on a Mac or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.
For more information, see Amazon EC2 Key Pairs (p. 433).

If you’ll connect to your Linux instance from a computer running Mac or Linux, you’ll specify the .pem file to your SSH client with the -i option and the path to your private key. If you’ll connect to your Linux instance from a computer running Windows, you can use either MindTerm or PuTTY. If you plan to use PuTTY, you’ll need to install it and use the following procedure to convert the .pem file to a .ppk file.

**Optional** To prepare to connect to a Linux instance from Windows using PuTTY

2. Start PuTTYgen (for example, from the Start menu, click All Programs > PuTTY > PuTTYgen).
3. Under *Type of key to generate*, select SSH-2 RSA.
4. Click **Load**. By default, PuTTYgen displays only files with the extension .ppk. To locate your .pem file, select the option to display files of all types.
5. Select the private key file that you created in the previous procedure and click **Open**. Click **OK** to dismiss the confirmation dialog box.
6. Click **Save private key**. PuTTYgen displays a warning about saving the key without a passphrase. Click **Yes**.
7. Specify the same name for the key that you used for the key pair. PuTTY automatically adds the .ppk file extension.

**Create a Security Group**

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your instance from your IP address using SSH. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere.

Note that if you plan to launch instances in multiple regions, you’ll need to create a security group in each region. For more information about regions, see Regions and Availability Zones (p. 7).

**Tip**

You’ll need the public IP address of your local computer, which you can get using a service. For example, we provide the following service: [http://checkip.amazonaws.com/](http://checkip.amazonaws.com/). To locate another service that provides your IP address, use the search phrase “what is my IP address.” If you are connecting through an Internet service provider (ISP) or from behind a firewall without a static IP address, you need to find out the range of IP addresses used by client computers.
To create a security group with least privilege

1. Open the Amazon EC2 console.
2. From the navigation bar, select a region for the security group. Security groups are specific to a region; for example, if you plan to launch an instance in the US West (Oregon) Region, you must create a security group for the instance in the US West (Oregon) Region.

3. Click Security Groups in the navigation pane.
5. Enter a name for the new security group and a description. Choose a name that is easy for you to remember, such as your IAM user name, followed by _SG_, plus the region name. For example, me_SG_uswest2.
6. On the Inbound tab, create the following rules (click Add Rule for each new rule), and click Create when you’re done:
   - Select HTTP from the Type list, and make sure that Source is set to Anywhere (0.0.0.0/0).
   - Select HTTPS from the Type list, and make sure that Source is set to Anywhere (0.0.0.0/0).
   - Select SSH from the Type list. In the Source box, ensure Custom IP is selected, and specify the public IP address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing prefix /32. For example, if your IP address is 203.0.113.25, specify 203.0.113.25/32. If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24.

Caution
For security reasons, we don’t recommend that you allow SSH access from all IP addresses (0.0.0.0/0) to your instance, except for testing purposes and only for a short time.

For more information, see Amazon EC2 Security Groups (p. 440).
Getting Started with Amazon EC2 Linux Instances

Let's get started with Amazon Elastic Compute Cloud (Amazon EC2) by launching, connecting to, and using a Linux instance. We'll use the AWS Management Console, a point-and-click web-based interface, to complete the example architecture shown in the following diagram:

The instance is an Amazon EBS-backed instance (meaning that the root volume is an Amazon EBS volume). We'll also create and attach an additional Amazon EBS volume. You can either specify the Availability Zone in which your instance runs, or let us select an Availability Zone for you. When you launch your instance, you secure it by specifying a key pair and security group. (This exercise assumes that you created a key pair and a security group when getting set up; see Get Set Up for Amazon EC2.) When you connect to your instance, you must specify the private key of the key pair that you specified when launching your instance.

To complete this exercise, perform the following tasks:

1. Launch an Amazon EC2 Instance (p. 25)
2. Connect to Your Instance (p. 26)
3. Add a Volume to Your Instance (p. 29)
4. Clean Up Your Instance and Volume (p. 32)
Launch an Amazon EC2 Instance

You can launch a Linux instance using the AWS Management Console as described in this topic. Before you begin, be sure that you’ve completed the steps in Get Set Up for Amazon EC2. After you’ve launched your instance, you can connect to it and use it. For more information, see Connect to Your Instance (p. 26).

If you’d prefer to launch and connect to a Windows instance, see Getting Started with Amazon EC2 Windows Instances.

Important
When you sign up for AWS, you can get started with Amazon EC2 for free using the AWS Free Usage Tier. If you created your AWS account less than 12 months ago, and have not already exceeded the Free Usage Tier benefits for Amazon EC2 and Amazon EBS, it will not cost you anything to complete this tutorial, because we help you select options that are within the Free Usage Tier benefits. Otherwise, you’ll incur the standard Amazon EC2 usage fees from the time that you launch the instance until you terminate the instance (which is the final task of this tutorial), even if it remains idle. The total charges to complete this tutorial outside the Free Usage Tier are minimal (typically only a few dollars).

The following procedure is intended to help you launch your first instance quickly and doesn’t go through all possible options. For more information about the advanced options, see Launching an Instance.

To launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console dashboard, click Launch Instance.
3. The Select an Amazon Machine Image (AMI) page displays a list of basic configurations called Amazon Machine Images (AMIs) that serve as templates for your instance. Select the 64-bit Amazon Linux AMI. Notice that this configuration is marked “Free tier eligible.”
4. On the Select an Instance Type page, you can select the hardware configuration of your instance. The t1.micro instance is selected by default. Click Review and Launch to let the wizard complete other configuration settings for you, so you can get started quickly.
5. On the Review Instance Launch page, you can review the settings for your instance.

Under Security Groups, you’ll see that the wizard created and selected a security group for you. Instead, select the security group that you created when getting set up using the following steps:

a. Click Edit security groups.

b. On the Configure Security Group page, ensure the Select an existing security group option is selected.

c. Select your security group from the list of existing security groups, and click Review and Launch.

7. In the Select an existing key pair or create a new key pair dialog box, select Choose an existing key pair, then select the key pair you created when getting set up.

   Alternatively, you can create a new key pair. Select Create a new key pair, enter a name for the key pair, and then click Download Key Pair. This is the only chance for you to save the private key file, so be sure to download it. Save the private key file in a safe place. You'll need to provide the name of your key pair when you launch an instance and the corresponding private key each time you connect to the instance.

   A key pair enables you to connect to a Linux instance through SSH. Therefore, don't select the Proceed without a key pair option. If you launch your instance without a key pair, then you can't connect to it.

   When you are ready, select the acknowledgment check box, and then click Launch Instances.

8. A confirmation page lets you know that your instance is launching. Click View Instances to close the confirmation page and return to the console.

9. On the Instances screen, you can view the status of your instance. It takes a short time for an instance to launch. When you launch an instance, its initial state is pending. After the instance starts, its state changes to running, and it receives a public DNS name. (If the Public DNS column is hidden, click the Show/Hide icon and select Public DNS.)

**Connect to Your Instance**

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

If you receive an error while attempting to connect to your instance, see Troubleshooting Connecting to Your Instance.

Before you try to connect to your instance, be sure that you've completed the following tasks:

- **Get the public DNS name of the instance**
  You can get the public DNS for your instance using the Amazon EC2 console (check the Public DNS column; if this column is hidden, click the Show/Hide icon and select Public DNS). If you prefer, you can use the `ec2-describe-instances` command.

- **Locate the private key**
  You'll need the fully-qualified path of the `.pem` file for the key pair that you specified when you launched the instance.

- **Enable inbound SSH traffic from your IP address to your instance**
  Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Authorizing Network Access to Your Instances.

There are several ways to connect to a Linux instance. Choose the method that meets your needs:

- **Option 1: Connect Using Your Browser** (p. 27)
- **Option 2: Connect from Windows Using PuTTY** (p. 27)
- **Option 3: Connect from Mac or Linux Using an SSH Client** (p. 29)

**Next Step**

After you've successfully launched and connected to your instance, you can do any of the following:
Option 1: Connect Using Your Browser

You must have Java installed and enabled in the browser. If you don’t have Java already, you can contact your system administrator to get it installed, or follow the steps outlined in the following pages: Install Java and Enable Java in your web browser.

To connect to your Linux instance using a web browser

1. From the Amazon EC2 console, click Instances in the navigation pane.
2. Select the instance, and then click Connect.
3. Click A Java SSH client directly from my browser (Java required).
4. Amazon EC2 automatically detects the public DNS name of your instance and populates Public DNS for you. It also detects the key pair that you specified when you launched the instance. Complete the following, and then click Launch SSH Client.
   a. In User name, enter ec2-user.
      Tip
      For Amazon Linux, the default user name is ec2-user. For RHEL5, the user name is often root but might be ec2-user. For Ubuntu, the user name is ubuntu. For SUSE Linux, the user name is root. Otherwise, check with your AMI provider.
   b. In Private key path, enter the fully qualified path to your private key (.pem) file.
   c. Click Store in browser cache to store the location of the private key in your browser cache. This enables Amazon EC2 to detect the location of the private key in subsequent browser sessions, until you clear your browser’s cache.
5. When prompted to add the host to your set of known hosts, click No.
6. If necessary, click Yes to trust the certificate.
7. Click Run to run the MindTerm client.
8. If you accept the license agreement, click Accept.
9. If this is your first time running MindTerm, a series of dialog boxes asks you to confirm setup for your home directory and other settings. Confirm these settings. A window opens and you are connected to your instance.

Option 2: Connect from Windows Using PuTTY

PuTTY doesn’t use .pem files, it uses .ppk files. If you haven’t already generated a .ppk file, do so now. For more information, see To prepare to connect to a Linux instance from Windows using PuTTY.

To connect to your Linux instance using PuTTY

1. Start PuTTY (from the Start menu, click All Programs > PuTTY > PuTTY).
2. In the Category pane, select Session and complete the following fields:
   a. In the Host Name box, enter ec2-user@public_dns_name.
b. Under **Connection type**, select **SSH**.

c. Ensure that **Port** is 22.

3. In the **Category** pane, expand **Connection**, expand **SSH**, and then select **Auth**. Complete the following:

a. Click **Browse**.
b. Select the `.ppk` file that you generated for your key pair, and then click **Open**.
c. Click **Open** to start the PuTTY session.

4. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host you are connecting to. Click **Yes**. A window opens and you are connected to your instance.
Option 3: Connect from Mac or Linux Using an SSH Client

Your Mac or Linux computer most likely includes an SSH client by default. You can check for an SSH client by typing `ssh` at the command line. If your computer doesn't recognize the command, the OpenSSH project provides a free implementation of the full suite of SSH tools. For more information, see http://www.openssh.org.

Open your command shell and run the following command:

```
$ ssh -i /path/key_pair.pem ec2-user@public_dns_name
```

**Tip**
For Amazon Linux, the default user name is `ec2-user`. For RHEL5, the user name is often `root` but might be `ec2-user`. For Ubuntu, the user name is `ubuntu`. For SUSE Linux, the user name is `root`. Otherwise, check with your AMI provider.

Add a Volume to Your Instance

Now that you've launched and connected to your Linux instance, you can run the following command on your instance to view its mounted volumes.

```
[ec2-user ~]$ df -h
```

For a micro instance, your output should look something like this.

```
Filesystem             Size   Used  Avail Use% Mounted on
/dev/xvda1             8.0G   1.1G   6.9G  14% /
tmpfs                  298M      0   298M   0% /dev/shm
```

The `/dev/xvda1` volume is the root device volume. It contains the image used to boot the instance. Notice that there's some room to install additional software on your instance. For example, you can use the `yum` command to download and install packages.

If you need additional storage for your data, a simple solution is to add Amazon EBS volumes to your instance. An Amazon EBS volume serves as network-attached storage for your instance. Let's add a volume to the Linux instance that you've launched. First we'll use the EC2 console to create the volume and attach it to the instance, and then we'll mount the volume to make it available.

To create and attach an Amazon EBS volume

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar, select the region in which you created your instance, and then click **Instances** in the navigation pane.
   The console displays the list of current instances in that region. Select your Linux instance. In the **Description** tab in the bottom pane note the **Availability Zone** for the instance.
3. In the navigation pane, under **Elastic Block Store**, click **Snapshots**. Select **Public Snapshots** from the filter list. Select a snapshot from the list and note its snapshot ID. The Free Usage Tier provides up to 30 GB of Amazon Elastic Block Storage; therefore, to avoid being charged for this tutorial, choose a snapshot that is smaller than 30 GB.
Note that this tutorial assumes that you create the volume using a snapshot as described in this step. If you create an empty volume instead, we'll ask you to perform an additional step in the next procedure.

4. Click **Create Volume**.

5. The **Create Volume** dialog box is preconfigured with the snapshot ID and volume size of the snapshot you selected. Configure the following, and then click **Create**:
   - Select the **Standard** volume type to create a standard EBS volume.
   - Select the same **Availability Zone** that you used when you created your instance. Otherwise, you can't attach the volume to your instance.

6. In the navigation pane, under **Elastic Block Store**, click **Volumes**. Notice that your newly created volume appears there and the state of the volume is **available**, so it's ready to be attached to an instance.

7. Right-click the newly created volume and select **Attach Volume**.

8. In the **Attach Volume** dialog box, configure the following, and then click **Attach**:
   - Start typing in the name or ID of your instance, then select it from the list of suggested options.
   - Specify an unused device name for that instance. We'll use `/dev/sdf` in this tutorial. If you select a different device name, be sure to note it as you'll need this information in the next procedure.

   You'll notice that in the **Details** pane for your volume, the state of the volume is **in-use**, and the volume is attached to your instance with the device name `/dev/sdf`. However, if you return to your instance and run the `df -h` command again, you won't see the volume yet. That's because we need to mount the volume for `df -h` to see it. The `lsblk` command, however, can see all block devices attached to the instance.

   **Note**
   Some Linux distributions do not provide the `lsblk` command by default. If the `lsblk` command does not work, you can use `sudo fdisk -l | grep Disk` instead.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvdf   202:80   0  100G  0 disk
xvdf1  202:81   0   10G  0 part
xvdal  202:1    0    8G  0 disk /
```

In the above example, `lsblk` reports that there are two block devices attached to the instance; `xvdal` is mounted as the root file system (note the `MOUNTPOINT` value of `/`) and `xvdf` (which contains the disk partition, `xvdf1`) is not mounted at all.

**To make a volume available**

1. Identify the device to mount. In the previous procedure, the new volume was attached to `/dev/sdf`. Depending on the block device drivers on your instance’s operating system, the device may appear at a different location (such as `/dev/xvdf` in the previous example) than what you specified in the console (`/dev/sdf`); in some cases, even the trailing letter may change (for example, `/dev/xvdj`). Amazon Linux instances always create links from the device path that you specified in the console to the new device path, but other distributions (such as Ubuntu or Red Hat) are not as predictable.

   Use the `lsblk` command to list the available devices.
Note
Some Linux distributions do not provide the `lsblk` command by default. If the `lsblk` command does not work, you can use `sudo fdisk -l | grep Disk` instead.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN  RM  SIZE      RO TYPE  MOUNTPOINT
xvdf    202:80   0  100G       0 disk         
xvdf1   202:81   0   10G       0 part         
xvda1   202:1    0    8G       0 disk /
```

The `xvdf` device is not mounted, and there is a 10 GB partition at `xvdf1`. Sometimes when you create a volume from a snapshot, the data on the volume is contained in a partition such as this instead of the root of the volume. In this case, you mount the `/dev/xvdf1` partition (the `lsblk` command output omits the `/dev/` portion of the file path). If there was not a partition on `xvdf`, then you would mount `/dev/xvdf`.

2. (Optional) If you created an empty volume instead of creating a volume from a snapshot in the previous procedure, you need to format the volume using `mkfs` before you can mount it. Use the following command to create an ext4 file system on the volume. Substitute the device name (such as `/dev/xvdf`) for `device_name`.

**Caution**
This step assumes that you're mounting an empty volume. If you're mounting a volume that already has data on it (for example, a volume that was restored from a snapshot), don't use `mkfs` before mounting the volume (skip to the next step instead). Otherwise, you'll format the volume and delete the existing data. For more information, see Making the Volume Available on Linux.

```
[ec2-user ~]$ sudo mkfs -t ext4 device_name
```

3. To mount the device as `/mnt/my-data`, run the following commands.

```
[ec2-user ~]$ sudo mkdir /mnt/my-data
[ec2-user ~]$ sudo mount /dev/xvdf1 /mnt/my-data
```

Be sure to specify the device name you identified in Step 1 (p. 30); otherwise, you might receive the following error when you run this mount command: "mount: you must specify the filesystem type". If you see this error, repeat Step 1 (p. 30) and use the correct device path (remember to add the `/dev/` to the device name you get from the `lsblk` command).

4. Now when you run the `df -h` command, you'll see output like the following.

```
[ec2-user ~]$ df -h
Filesystem   Size  Used  Avail  Use%  Mounted on
/dev/xvda1   7.9G   1.1G  6.8G   14% /
/tmppfs       298M     0   298M    0% /dev/shm
/dev/xvdf1   10G   76M   10G    1% /mnt/my-data
```

5. To view the contents of the new volume, run the following command.

```
[ec2-user ~]$ ls /mnt/my-data
```
At this point, you have completed the example architecture for this tutorial. You can continue to customize and use your instance for as long as you wish.

**Important**

Remember, if you launched an instance in the Free Usage Tier, there are no charges. Otherwise, as soon as your instance starts to boot, you’re billed for each hour or partial hour that you keep the instance running, even if the instance is idle. You’ll stop incurring charges for a regular instance as soon as the instance status changes to **shutting down** or **terminated**.

When you’re finished with your instance, don’t forget to clean up any resources you’ve used and terminate the instance, as shown in the next step, *Clean Up Your Instance and Volume* (p. 32).

---

## Clean Up Your Instance and Volume

After you’ve finished with the instance and the Amazon EBS volume that you created for this tutorial, you should clean up. First, terminate the instance, which detaches the volume from the instance, and then delete the volume.

Terminating an instance effectively deletes it because you can’t reconnect to an instance after you’ve terminated it. This differs from stopping the instance; when you stop an instance, it is shut down and you are not billed for hourly usage or data transfer (but you are billed for any Amazon EBS volume storage). Also, you can restart a stopped instance at any time. For more information about the differences between stopping and terminating an instance, see *Stopping Instances*.

**To terminate the instance**

1. Locate your instance in the list of instances on the **Instances** page. If you can’t find your instance, verify that you have selected the correct region.
2. Right-click the instance, and then click **Terminate**.
3. Click **Yes, Terminate** when prompted for confirmation.

EBS volumes can persist even after your instance is terminated. If you created and attached an EBS volume in the previous step, it was detached when you terminated the instance. However, you must delete the volume, or you’ll be charged for volume storage if the storage amount exceeds the limit of the Free Usage Tier. After you delete a volume, its data is gone and the volume can’t be attached to any instance.

**To delete the volume**

1. Locate the volume that you created in the list of volumes on the **Volumes** page. If you can’t find your volume, verify that you have selected the correct region.
2. Right-click the volume, and then click **Delete Volume**.
3. Click **Yes, Delete** when prompted for confirmation.

Amazon EC2 begins deleting the volume.
Best Practices for Amazon EC2

This checklist is intended to help you get the maximum benefit from and satisfaction with Amazon EC2.

- Manage access to AWS resources and APIs using identity federation, IAM users, and IAM roles. Establish credential management policies and procedures for creating, distributing, rotating, and revoking AWS access credentials. For more information, see IAM Best Practices in the Using IAM guide.
- Launch your instances into a VPC instead of EC2-Classic. For more information about the benefits, see Amazon EC2 and Amazon Virtual Private Cloud (VPC) (p. 485).
- Implement the least permissive rules for your security group. For more information, see Security Group Rules (p. 441).
- Understand the implications of the root device type for data persistence, backup, and recovery. For more information, see Storage for the Root Device (p. 50).
- Use separate Amazon EBS volumes for the operating system versus data.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see Amazon EC2 Instance IP Addressing (p. 489).
- Regularly patch, update, and secure the operating system and applications on your instance. For more information about updating Amazon Linux, see Managing Software (p. 332). For more information about updating Windows Server, go to Windows Server Update Services on the Microsoft website.
- Regularly back up your instance using Amazon EBS snapshots (p. 559) or a backup tool.
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Monitor and respond to events. For more information, see Monitoring Amazon EC2 (p. 353).
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see Elastic Network Interfaces (ENI) (p. 503). For an automated solution, you can use Auto Scaling. For more information, see the Auto Scaling Developer Guide.
- Regularly test the process of recovering your instances and Amazon EBS volumes if they fail.
- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see Instance Metadata and User Data (p. 268) and Tagging Your Amazon EC2 Resources (p. 610).
Tutorial: Installing a LAMP Web Server

The following procedures help you install the Apache web server with PHP and MySQL support on your Amazon EC2 instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Prerequisites

This tutorial assumes that you have already launched an instance with a public DNS name that is reachable from the Internet. For more information, see Launch an Amazon EC2 Instance (p. 25). You must also have configured your security group to allow **SSH** (port 22), **HTTP** (port 80), and **HTTPS** (port 443) connections. For more information about these prerequisites, see Setting Up with Amazon EC2 (p. 19).

**Important**
These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation. **If you are trying to set up a LAMP web server on an Ubuntu instance, this tutorial will not work for you.** For information about LAMP web servers on Ubuntu, go to the Ubuntu community documentation ApacheMySQLPHP topic.

To install and start the LAMP web server

1. **Connect to your instance** (p. 26).
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure you have the latest security updates and bug fixes.

   **Note**
   The **-y** option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

   ![Command Example](command.png)

3. Now that your instance is current, you can install the Apache web server, MySQL, and PHP software packages. Use the **yum groupinstall** command to install multiple software packages and all related dependencies at the same time.
4. Install the `php-mysql` package.

```bash
[ec2-user ~]$ sudo yum install -y php-mysql
```

5. Start the Apache web server.

```bash
[ec2-user ~]$ sudo service httpd start
Starting httpd: [ OK ]
```

6. Use the `chkconfig` command to configure the Apache web server to start at each system boot.

```bash
[ec2-user ~]$ sudo chkconfig httpd on
```

**Tip**

The `chkconfig` command does not provide any confirmation message when you successfully enable a service. You can verify that `httpd` is on by running the following command.

```bash
[ec2-user ~]$ chkconfig --list httpd
httpd       0:off 1:off 2:on 3:on 4:on 5:on 6:off
```

Here, `httpd` is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

7. Test your web server. In a web browser, enter the public DNS address (or the public IP address) of your instance; you should see the Apache test page. You can get the public DNS for your instance using the Amazon EC2 console (check the **Public DNS** column; if this column is hidden, click the **Show/Hide** icon and select **Public DNS**).

**Tip**

If you are unable to see the Apache test page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For information about adding an HTTP rule to your security group, see Adding Rules to a Security Group (p. 445).

**Important**

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

---

**Note**

Non-Amazon Linux instances may have subtle differences in their group names. If the above command fails because of an invalid group name, use the `yum grouplist` command and scan the output for similar groups, such as "MySQL Database server" instead of "MySQL Database", and use the appropriate group name for your distribution.
Note
This test page appears only when there is no content in /var/www/html. When you add content to the document root, your content appears at the public DNS address of your instance instead of this test page.

Apache httpd serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is /var/www/html, which is owned by root by default.

```
[ec2-user ~]$ ls -l /var/www
total 16
drwxr-xr-x 2 root root 4096 Jul 12 01:00 cgi-bin
drwxr-xr-x 3 root root 4096 Aug  7 00:02 error
drwxr-xr-x 2 root root 4096 Jan  6  2012 html
drwxr-xr-x 3 root root 4096 Aug  7 00:02 icons
```

To allow ec2-user to manipulate files in this directory, you need to modify the ownership and permissions of the directory. There are many ways to accomplish this task; in this tutorial, you add a www group to your instance, and you give that group ownership of the /var/www directory and add write permissions for the group. Any members of that group will then be able to add, delete, and modify files for the web server.

To set file permissions

1. Add the www group to your instance.

```
[ec2-user ~]$ sudo groupadd www
```

2. Add your user (in this case, ec2-user) to the www group.

```
[ec2-user ~]$ sudo usermod -a -G www ec2-user
```
Important
You need to log out and log back in to pick up the new group. You can use the `exit` command, or close the terminal window.

3. Log out and then log back in again, and verify your membership in the `www` group.
   a. Log out.

   ```bash
   [ec2-user ~]$ exit
   ```

   b. Reconnect to your instance, and then run the following command to verify your membership in the `www` group.

   ```bash
   [ec2-user ~]$ groups
c2-user wheel www
   ```

4. Change the group ownership of `/var/www` and its contents to the `www` group.

   ```bash
   [ec2-user ~]$ sudo chown -R root:www /var/www
   ```

5. Change the directory permissions of `/var/www` and its subdirectories to add group write permissions and to set the group ID on future subdirectories.

   ```bash
   [ec2-user ~]$ sudo chmod 2775 /var/www
   [ec2-user ~]$ find /var/www -type d -exec sudo chmod 2775 {} +
   ```

6. Recursively change the file permissions of `/var/www` and its subdirectories to add group write permissions.

   ```bash
   [ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} +
   ```

Now `ec2_user` (and any future members of the `www` group) can add, delete, and edit files in the Apache document root. Now you are ready to add content, such as a static website or a PHP application.

**To test your LAMP web server**

If your server is installed and running, and your file permissions are set correctly, your `ec2-user` account should be able to create a simple PHP file in the `/var/www/html` directory that will be available from the Internet.

1. Create a simple PHP file in the Apache document root.

   ```bash
   ```

**Tip**
If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in To set file permissions (p. 36).
2. In a web browser, enter the URL of the file you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

```plaintext
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page.

3. Delete the `phpinfo.php` file. Although this can be useful information to you, it should not be broadcast to the Internet for security reasons.

```plaintext
[ec2-user ~]$ rm /var/www/html/phpinfo.php
```

**To secure the MySQL server**

The default installation of the MySQL server has several features that are great for testing and development, but they should be disabled or removed for production servers. The `mysql_secure_installation` command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MySQL server, performing this procedure is a good idea.

1. Start the MySQL server so that you can run `mysql_secure_installation`.

```plaintext
[ec2-user ~]$ sudo service mysqld start
```

```
Initializing MySQL database:  Installing MySQL system tables... OK
Filling help tables... OK

To start mysqld at boot time you have to copy support-files/mysql.server to the right place for your system

PLEASE REMEMBER TO SET A PASSWORD FOR THE MySQL root USER!
...
```

```
Starting mysqld: [ OK ]
```
2. Run `mysql_secure_installation`.

```bash
[ec2-user ~]$ sudo mysql_secure_installation
```

a. When prompted, enter a password for the root account.

   i. Enter the current root password. By default, the root account does not have a password set, so press `Enter`

   ii. Type `Y` to set a password, and enter a secure password twice. For more information about creating a secure password, go to http://www.pctools.com/guides/password/. Make sure to store this password in a safe place.

b. Type `Y` to remove the anonymous user accounts.

c. Type `Y` to disable remote root login.

d. Type `Y` to remove the test database.

e. Type `Y` to reload the privilege tables and save your changes.

3. (Optional) Stop the MySQL server if you do not plan to use it right away. You can restart the server when you need it again.

```bash
[ec2-user ~]$ sudo service mysqld stop
Stopping mysqld: [ OK ]
```

4. (Optional) If you want the MySQL server to start at every boot, enter the following command.

```bash
[ec2-user ~]$ sudo chkconfig mysqld on
```

You should now have a fully functional LAMP web server. If you add content to the Apache document root at `/var/www/html`, you should be able to view that content at the public DNS address for your instance.

Tutorial: Hosting a WordPress Blog with Amazon EC2

The following procedures will help you install, configure, and secure a WordPress blog on your Amazon EC2 instance.

Important
These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

This tutorial is a good introduction to using Amazon EC2 in that you have full control over a web server that hosts your WordPress blog, which is not typical with a traditional hosting service. Of course, that means that you are responsible for updating the software packages and maintaining security patches for your server as well. For a more automated WordPress installation that does not require direct interaction with the web server configuration, the AWS CloudFormation service provides a WordPress template that can also get you started quickly. For more information, see Get Started in the AWS CloudFormation User Guide. If you'd prefer to host your WordPress blog on a Windows instance, see Deploying a WordPress Blog on Your Amazon EC2 Windows Instance in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

Prerequisites
This tutorial assumes that you have launched an instance with a functional web server with PHP and MySQL support. Your Amazon EC2 security group should also allow HTTP and HTTPS traffic. If you do not already have a functional web server, see Tutorial: Installing a LAMP Web Server (p. 34) to create one and then return to this tutorial to install WordPress. For information about adding rules to your security group, see Adding Rules to a Security Group (p. 445).

To download and unzip the WordPress installation package

1. Download the latest WordPress installation package with the `wget` command. The following command should always download the latest release.

```
[ec2-user ~]$ wget https://wordpress.org/latest.tar.gz
--2013-08-09 17:19:01--  https://wordpress.org/latest.tar.gz
Resolving wordpress.org (wordpress.org)... 66.155.40.249, 66.155.40.250
Connecting to wordpress.org (wordpress.org)|66.155.40.249|:443... connected.
HTTP request sent, awaiting response... 200 OK
```
2. Unzip and unarchive the installation package. The installation folder is unzipped to a folder called `wordpress`.

```
[ec2-user ~]$ tar -xzf latest.tar.gz
[ec2-user ~]$ ls
latest.tar.gz  wordpress
```

**To create a MySQL user and database for your WordPress installation**

Your WordPress installation needs to store information, such as blog post entries and user comments, in a database. This procedure will help you create a database for your blog and a user that is authorized to read and save information to that database.

1. Start the MySQL server.

```
[ec2-user ~]$ sudo service mysqld start
```

2. Log in to the MySQL server as the root user. Enter your MySQL root password when prompted; this may be different than your root system password, or it may even be empty if you have not secured your MySQL server.

   **Important**
   If you have not secured your MySQL server yet, it is very important that you do so. For more information, see To secure the MySQL server (p. 38).

   ```
   [ec2-user ~]$ mysql -u root -p
   Enter password:
   ```

3. Create a user and password for your MySQL database. Your WordPress installation uses these values to communicate with your MySQL database. Enter the following command, substituting a unique user name and password.

   ```
   mysql> CREATE USER 'wordpress-user'@'localhost' IDENTIFIED BY 'your_strong_password';
   Query OK, 0 rows affected (0.00 sec)
   ```

   Make sure that you create a strong password for your user. Do not use the single quote character (') in your password, because this will break the preceding command. For more information about creating a secure password, go to http://www.pctools.com/guides/password/. Do not reuse an existing password, and make sure to store this password in a safe place.

4. Create your database. Give your database a descriptive, meaningful name, such as `wordpress-db`.

   **Note**
   The punctuation marks surrounding the database name in the command below are called backticks. The backtick (`) key is usually located above the Tab key on a standard keyboard.
Backticks are not always required, but they allow you to use otherwise illegal characters, such as hyphens, in database names.

```sql
mysql> CREATE DATABASE `wordpress-db`;
Query OK, 1 row affected (0.01 sec)
```

5. Grant full privileges for your database to the WordPress user you created earlier.

```sql
mysql> GRANT ALL PRIVILEGES ON `wordpress-db`.* TO "wordpress-user"@"local host";
Query OK, 0 rows affected (0.00 sec)
```

6. Flush the MySQL privileges to pick up all of your changes.

```sql
mysql> FLUSH PRIVILEGES;
Query OK, 0 rows affected (0.01 sec)
```

7. Exit the mysql client.

```sql
mysql> exit
Bye
```

To create and edit the wp-config.php file

The WordPress installation folder contains a sample configuration file called `wp-config-sample.php`. In this procedure, you copy this file and edit it to fit your specific configuration.

1. Copy the `wp-config-sample.php` file to a file called `wp-config.php`. This creates a new configuration file and keeps the original sample file intact as a backup.

   ```bash
   [ec2-user ~]$ cd wordpress/
   [ec2-user wordpress]$ cp wp-config-sample.php wp-config.php
   ```

2. Edit the `wp-config.php` file with your favorite text editor (such as `nano` or `vim`) and enter values for your installation. If you do not have a favorite text editor, `nano` is much easier for beginners to use.

   ```bash
   [ec2-user wordpress]$ nano wp-config.php
   ```

   a. Find the line that defines `DB_NAME` and change `database_name_here` to the database name you created in Step 4 (p. 41) of To create a MySQL user and database for your WordPress installation (p. 41).

   ```php
define('DB_NAME', 'wordpress-db');
```

   b. Find the line that defines `DB_USER` and change `username_here` to the database user you created in Step 3 (p. 41) of To create a MySQL user and database for your WordPress installation (p. 41).
define('DB_USER', 'wordpress-user');

c. Find the line that defines DB_PASSWORD and change password_here to the strong password you created in Step 3 (p. 41) of To create a MySQL user and database for your WordPress installation (p. 41).

define('DB_PASSWORD', 'your_strong_password');

d. Find the section called Authentication Unique Keys and Salts. These KEY and SALT values provide a layer of encryption to the browser cookies that WordPress users store on their local machines. Basically, adding long, random values here makes your site more secure. Visit https://api.wordpress.org/secret-key/1.1/salt/ to randomly generate a set of key values that you can copy and paste into your wp-config.php file. To paste text into a PuTTY terminal, place the cursor where you want to paste the text and right-click your mouse inside the PuTTY terminal.

For more information about security keys, go to http://codex.wordpress.org/Editing_wp-config.php#Security_Keys.

Note
The values below are for example purposes only; do not use these values for your installation.

define('AUTH_KEY', ' #U$$+[RXN8:b^-L 0(WU_,+ c+WFkI-c]o]-bHw+}/AjwTwSi2<Qb[mghEXcRh-');
define('SECURE_AUTH_KEY', 'Zsz_.P=1/|y.6g)XjlkwS1y5NJ76E6J.AV0pCK2ZB,*-*r 760P&6eJT8;+(nd1g');

To move your WordPress installation to the Apache document root

Now that you’ve unzipped the installation folder, created a MySQL database and user, and customized the WordPress configuration file, you are ready to move your installation files to your web server document root so you can run the installation script that completes your installation. The location of these files depends on whether you want your WordPress blog to be available at the root of your web server (for example, my.public.dns.amazonaws.com) or in a subdirectory or folder (for example, my.public.dns.amazonaws.com/blog).
Important
Choose the location where you want your blog to be available and only run the `mv` associated with that location. If you run both sets of commands below, you will get an error message on the second `mv` command because the files you are trying to move are no longer there.

1. To make your blog available at `my.public.dns.amazonaws.com`, move the files in the `wordpress` folder (but not the folder itself) to the Apache document root (`/var/www/html` on Amazon Linux instances).

   ```bash
   [ec2-user wordpress]$ mv * /var/www/html/
   ```

2. OR, to make your blog available at `my.public.dns.amazonaws.com/blog` instead, create a new folder called `blog` inside the Apache document root and move the files in the `wordpress` folder (but not the folder itself) to the new `blog` folder.

   ```bash
   [ec2-user wordpress]$ mkdir /var/www/html/blog
   [ec2-user wordpress]$ mv * /var/www/html/blog
   ```

Important
If you are not moving on to the next procedure immediately, stop the Apache web server (`httpd`) now for security purposes. After you move your installation to the Apache document root, the WordPress installation script is unprotected and an attacker could gain access to your blog if the Apache web server were running. To stop the Apache web server, enter the command `sudo service httpd stop`. If you are moving on to the next procedure, you do not need to stop the Apache web server.

To fix file permissions for the Apache web server

Some of the available features in WordPress require write access to the Apache document root (such as uploading media through the Administration screens). The web server runs as the `apache` user, so you need to add that user to the `www` group that was created in the LAMP web server tutorial (p. 34).

1. Add the `apache` user to the `www` group.

   ```bash
   [ec2-user wordpress]$ sudo usermod -a -G www apache
   ```

2. Change the group ownership of `/var/www` and its contents to the `www` group.

   ```bash
   [ec2-user wordpress]$ sudo chgrp -R www /var/www
   ```

3. Change the directory permissions of `/var/www` and its subdirectories to add group write permissions and to set the group ID on future subdirectories.

   ```bash
   [ec2-user wordpress]$ sudo chmod 2775 /var/www
   [ec2-user wordpress]$ find /var/www -type d -exec sudo chmod 2775 {} +
   ```

4. Recursively change the file permissions of `/var/www` and its subdirectories to add group write permissions.

   ```bash
   [ec2-user wordpress]$ find /var/www -type f -exec sudo chmod 0664 {} +
   ```
5. Restart the Apache web server to pick up the new group and permissions.

```
[ec2-user wordpress]$ sudo service httpd restart
Stopping httpd: [  OK  ]
Starting httpd: [  OK  ]
```

To run the WordPress installation script

1. Use the `chkconfig` command to ensure that the `httpd` and `mysqld` services start at every system boot.

```
[ec2-user wordpress]$ sudo chkconfig httpd on
[ec2-user wordpress]$ sudo chkconfig mysqld on
```

2. Verify that the MySQL server (`mysqld`) is running.

```
[ec2-user wordpress]$ sudo service mysqld status
mysqld (pid  4746) is running...
```

If the `mysqld` service is not running, start it.

```
[ec2-user wordpress]$ sudo service mysqld start
Starting mysqld: [  OK  ]
```

3. Verify that your Apache web server (`httpd`) is running.

```
[ec2-user wordpress]$ sudo service httpd status
httpd (pid  502) is running...
```

If the `httpd` service is not running, start it.

```
[ec2-user wordpress]$ sudo service httpd start
Starting httpd: [  OK  ]
```

4. Verify that the `php` and `php-mysql` packages are installed. Your output may look slightly different, but look for the `Installed Packages` section.

```
[ec2-user wordpress]$ yum list installed php php-mysql
Loaded plugins: priorities, security, update-motd, upgrade-helper

```

**Note**

If either of these packages are not listed as installed, install them with the following command and then restart the `httpd` service.
5. In a web browser, enter the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the blog folder). You should see the WordPress installation screen.

http://my.public.dns.amazonaws.com

6. Enter the remaining installation information into the WordPress installation wizard.

7. Click Install WordPress to complete the installation.
Congratulations, you should now be able to log into your WordPress blog and start posting entries.

If your WordPress blog becomes popular and you need more compute power, you might consider migrating to a larger instance type; for more information, see Resizing Your Instance (p. 118). If your blog requires more storage space than you originally accounted for, you could expand the storage space on your instance; for more information, see Expanding the Storage Space of a Volume (p. 548). If your MySQL database needs to grow, you could consider moving it to Amazon RDS to take advantage of the service’s autoscaling abilities.

Amazon Machine Images (AMI)

An Amazon Machine Image (AMI) provides the information required to launch an instance, which is a virtual server in the cloud. You specify an AMI when you launch an instance, and you can launch as many instances from the AMI as you need.

An AMI includes the following:

- A template for the root volume for the instance (for example, an operating system, an application server, and applications)
- Launch permissions that control which AWS accounts can use the AMI to launch instances
- A block device mapping that specifies the volumes to attach to the instance when it’s launched

Using an AMI

The following diagram summarizes the AMI lifecycle. After you create and register an AMI, you can use it to launch new instances. (You can also launch instances from an AMI if the AMI owner grants you launch permissions.) You can copy an AMI to the same region or to different regions. When you are finished launching instance from an AMI, you can deregister the AMI.

You can search for an AMI that meets the criteria for your instance. You can search for AMIs provided by AWS or AMIs provided by the community. For more information, see AMI Types (p. 50) and Finding a Suitable AMI (p. 53).

When you are connected to an instance, you can use it just like you use any other server. For information about launching, connecting, and using your instance, see Amazon EC2 Instances (p. 97).
Creating Your Own AMI

You can customize the instance that you launch from a public AMI and then save that configuration as a custom AMI for your own use. Instances that you launch from your AMI use all the customizations that you've made.

The root storage device of the instance determines the process you follow to create an AMI. The root volume of an instance is either an Amazon EBS volume or an instance store volume. For information, see Amazon EC2 Root Device Volume (p. 13).

To create an Amazon EBS-backed AMI, see Creating an Amazon EBS-Backed Linux AMI (p. 69). To create an instance store-backed AMI, see Creating an Instance Store-Backed Linux AMI (p. 72).

To help categorize and manage your AMIs, you can assign custom tags to them. For more information, see Tagging Your Amazon EC2 Resources (p. 610).

Buying, Sharing, and Selling AMIs

After you create an AMI, you can keep it private so that only you can use it, or you can share it with a specified list of AWS accounts. You can also make your custom AMI public so that the community can use it. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see Shared AMIs (p. 54).

You can purchase an AMIs from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it to other Amazon EC2 users. For more information about buying or selling AMIs, see Paid AMIs (p. 64).

Deregistering Your AMI

You can deregister an AMI when you have finished with it. After you deregister an AMI, you can't use it to launch new instances. For more information, see Deregistering Your AMI (p. 83).

Amazon Linux

The Amazon Linux AMI is a supported and maintained Linux image provided by AWS. The following are some of the features of Amazon Linux:

- A stable, secure, and high-performance execution environment for applications running on Amazon EC2.
- Provided at no additional charge to Amazon EC2 users.
- An Amazon EBS-backed, PV-GRUB AMI that includes Linux 3.4, AWS tools, and repository access to multiple versions of MySQL, PostgreSQL, Python, Ruby, and Tomcat.
- Updated on a regular basis to include the latest components, and these updates are also made available in the yum repositories for installation on running instances.
- Includes packages that enable easy integration with AWS services, such as the Amazon EC2 API and AMI tools, the Boto library for Python, and the Elastic Load Balancing tools.

For more information, see Amazon Linux (p. 84).
AMI Types

You can select an AMI to use based on the following characteristics:

- Region (see Regions and Availability Zones (p. 7))
- Operating system
- Architecture (32-bit or 64-bit)
- Launch Permissions (p. 50)
- Storage for the Root Device (p. 50)

Launch Permissions

The owner of an AMI determines its availability by specifying launch permissions. Launch permissions fall into the following categories.

<table>
<thead>
<tr>
<th>Launch Permission</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>The owner grants launch permissions to all AWS accounts.</td>
</tr>
<tr>
<td>explicit</td>
<td>The owner grants launch permissions to specific AWS accounts.</td>
</tr>
<tr>
<td>implicit</td>
<td>The owner has implicit launch permissions for an AMI.</td>
</tr>
</tbody>
</table>

Amazon and the Amazon EC2 community provide a large selection of public AMIs. For more information, see Shared AMIs (p. 54). Developers can charge for their AMIs. For more information, see Paid AMIs (p. 64).

Storage for the Root Device

All AMIs are categorized as either backed by Amazon EBS or backed by instance store. The former means that the root device for an instance launched from the AMI is an Amazon EBS volume created from an Amazon EBS snapshot. The latter means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3. For more information, see Amazon EC2 Root Device Volume (p. 13).

This section summarizes the important differences between the two types of AMIs. The following table provides a quick summary of these differences.

* By default, Amazon EBS-backed instance root volumes have the `DeleteOnTermination` flag set to `true`, which causes the volume to be deleted upon instance termination. For information about how to change this so that the volume persists following termination, see Changing the Root Device Volume to Persist (p. 16).

### Determining the Root Device Type of Your AMI

#### To determine the root device type of an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click **AMIs**, and select the AMI.
3. Check the value of **Root Device Type** in the **Details** tab as follows:
   - If the value is `ebs`, this is an Amazon EBS-backed AMI.
   - If the value is `instance store`, this is an instance store-backed AMI.

#### To determine the root device type of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-images` (AWS CLI)
- `ec2-describe-images` (Amazon EC2 CLI)
- `Get-EC2Image` (AWS Tools for Windows PowerShell)

### Size Limit

Amazon EC2 instance store-backed AMIs are limited to 10 GiB storage for the root device, whereas Amazon EBS-backed AMIs are limited to 1 TiB. Many Windows AMIs come close to the 10 GiB limit, so you’ll find that Windows AMIs are often backed by an Amazon EBS volume.

**Note**

All Windows Server 2008, Windows Server 2008 R2, and Windows Server 2012 AMIs are backed by an Amazon EBS volume by default because of their larger size.
Stopped State

You can stop an Amazon EBS-backed instance, but not an Amazon EC2 instance store-backed instance. Stopping causes the instance to stop running (its status goes from running to stopping to stopped). A stopped instance persists in Amazon EBS, which allows it to be restarted. Stopping is different from terminating; you can't restart a terminated instance. Because Amazon EC2 instance store-backed AMIs can't be stopped, they're either running or terminated. For more information about what happens and what you can do while an instance is stopped, see Stop and Start Your Instance (p. 319).

Default Data Storage and Persistence

Instances that use an instance store volume for the root device automatically have instance store available (the root volume contains the root partition and you can store additional data). Any data on an instance store volume is deleted when the instance fails or terminates (except for data on the root device). You can add persistent storage to your instance by attaching one or more Amazon EBS volumes.

Instances that use Amazon EBS for the root device automatically have an Amazon EBS volume attached. The volume appears in your list of volumes like any other. The instances don't use any available instance store volumes by default. You can add instance storage or additional Amazon EBS volumes using a block device mapping. For more information, see Block Device Mapping (p. 592). For information about what happens to the instance store volumes when you stop an instance, see Stop and Start Your Instance (p. 319).

Boot Times

Amazon EBS-backed AMIs launch faster than Amazon EC2 instance store-backed AMIs. When you launch an Amazon EC2 instance store-backed AMI, all the parts have to be retrieved from Amazon S3 before the instance is available. With an Amazon EBS-backed AMI, only the parts required to boot the instance need to be retrieved from the snapshot before the instance is available. However, the performance of an instance that uses an Amazon EBS volume for its root device is slower for a short time while the remaining parts are retrieved from the snapshot and loaded into the volume. When you stop and restart the instance, it launches quickly, because the state is stored in an Amazon EBS volume.

AMI Creation

To create Linux/Unix AMIs backed by instance store, you must create an AMI from your instance on the instance itself, but there aren't any API actions to help you. To create a Windows AMI backed by instance store, there's an API action that creates an AMI and another API action that registers the AMI.

AMI creation is much easier for AMIs backed by Amazon EBS. The CreateImage API action creates the AMI on both Linux/Unix and Windows. This API action creates your Amazon EBS-backed AMI and registers it. There's also a button in the AWS Management Console that lets you create an AMI from a running instance. For more information, see Creating an Amazon EBS-Backed Linux AMI (p. 69).

How You’re Charged

With AMIs backed by instance store, you’re charged for AMI storage and instance usage. With AMIs backed by Amazon EBS, you're charged for volume storage and usage in addition to the AMI and instance usage charges.

With Amazon EC2 instance store-backed AMIs, each time you customize an AMI and create a new one, all of the parts are stored in Amazon S3 for each AMI. So, the storage footprint for each customized AMI is the full size of the AMI. For Amazon EBS-backed AMIs, each time you customize an AMI and create a new one, only the changes are stored. So the storage footprint for subsequent AMIs you customize after the first is much smaller, resulting in lower AMI storage charges.
When an Amazon EBS-backed instance is stopped, you're not charged for instance usage; however, you're still charged for volume storage. We charge a full instance hour for every transition from a stopped state to a running state, even if you transition the instance multiple times within a single hour. For example, let's say the hourly instance charge for your instance is $0.10. If you were to run that instance for one hour without stopping it, you would be charged $0.10. If you stopped and restarted that instance twice during that hour, you would be charged $0.30 for that hour of usage (the initial $0.10, plus 2 x $0.10 for each restart).

## Finding a Suitable AMI

Before you select an AMI, consider the following requirements you might have for the instances that you'll launch:

- The region
- The operating system
- The architecture: 32-bit (i386) or 64-bit (x86_64)
- The root device type: Amazon EBS or instance store
- The provider: Amazon Web Services, Oracle, IBM, Microsoft, or the community

## Finding an AMI Using the Amazon EC2 Console

**To find a suitable AMI using the console**

1. Open the Amazon EC2 console.
2. From the navigation bar, select a region. You can select any region that's available to you, regardless of your location. This is the region in which you'll launch your instance.
3. In the navigation pane, click AMIs.
4. (Optional) Use the Filter options to scope the list of displayed AMIs to the AMIs that interest you. For example, to list all AMIs provided by AWS, select Public images and then Amazon images.
5. (Optional) Click the Show/Hide Columns icon to select which image attributes to display, such as the root device type. Alternatively, you can select an AMI from the list and view its properties in the Details tab.
6. Before you select an AMI, it's important that you check whether it's backed by instance store or by Amazon EBS and that you are aware of the effects of this difference. For more information, see Storage for the Root Device (p. 50).
7. To launch an instance from this AMI, select it and then click Launch. For more information, see Launch Your Instance (p. 300). If you're not ready to launch the instance now, write down the AMI ID (ami-xxxxxxxx) for later.

## Finding an AMI Using the Command Line

You can use one of the following commands to find your AMIs and Amazon’s public AMIs.

- `describe-images` (AWS CLI)
  
  ```sh
daemon:~$ aws ec2 describe-images --owners self amazon
  ```

- `ec2-describe-images` (Amazon EC2 CLI)
To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, add the following filters to display only Windows AMIs backed by Amazon EBS:

- `describe-images` (AWS CLI)

  ```bash
  --filters "Name=platform,Values=Windows,Name=root-device-type,Values=ebs"
  ```

- `ec2-describe-images` (Amazon EC2 CLI)

  ```bash
  --filter "platform=windows" --filter "root-device-type=ebs"
  ```

After locating an AMI that meets your needs, write down its ID (ami-xxxxxxxx). You can use this AMI to launch an instance. For more information, see Launching an Instance Using the AWS CLI in the **AWS Command Line Interface User Guide** or Launching an Instance Using the Amazon EC2 CLI in the **Amazon Elastic Compute Cloud Command Line Reference**.

### Shared AMIs

A *shared AMI* is an AMI that a developer created and made available for other developers to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content.

You use a shared AMI at your own risk. Amazon can't vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center and perform the appropriate due diligence.

We recommend that you get an AMI from a trusted source. If you have questions or observations about a shared AMI, use the AWS forums.

Amazon's public images have an aliased owner, which appears as `amazon` in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

### Finding Shared AMIs

You can use the Amazon EC2 console or the Amazon EC2 CLI to find shared AMIs.
Finding a Shared AMI Using the Console

To find a shared private AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. In the first filter, select Private images. All AMIs that have been shared with you are listed.

To find a shared public AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. To find shared AMIs, select Public images from the Filter list.
4. Use filters to list only the types of AMIs that interest you. For example, select Amazon images to display only Amazon's public images.

Finding a Shared AMI Using the AWS CLI

To find a shared public AMI using the command line tools

Use the describe-images command to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

The following command lists all public AMIs using the --executable-users option. This list includes any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

The following command lists the AMIs for which you have explicit launch permissions. This list excludes any such AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

The following command lists the AMIs owned by Amazon. Amazon's public AMIs have an aliased owner, which appears as amazon in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

```
aws ec2 describe-images --owners amazon
```

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only Windows-based AMIs.

```
--filters "Name=platform,Values=windows"
```
**Finding a Shared AMI Using the Amazon EC2 CLI**

To find a shared public AMI using the command line tools

Use the `ec2-describe-images` command to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

The following command lists all public AMIs using the `-x all` option. This list includes any public AMIs that you own.

```
ec2-describe-images -x all
```

The following command lists the AMIs for which you have explicit launch permissions. This list excludes any such AMIs that you own.

```
ec2-describe-images -x self
```

The following command lists the AMIs owned by Amazon. Amazon's public AMIs have an aliased owner, which appears as `amazon` in the account field. This enables you to find AMIs from Amazon easily. Other users can't alias their AMIs.

```
ec2-describe-images -o amazon
```

The following command lists the AMIs owned by the specified AWS account.

```
ec2-describe-images -o <target_uid>
```

The `<target_uid>` is the account ID that owns the AMIs for which you are looking.

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only Windows-based AMIs.

```
--filter "platform=windows"
```

**Using Shared AMIs**

Before you use a shared AMI, take the following steps to confirm that there are no pre-installed credentials that would allow unwanted access to your instance by a third party and no pre-configured remote logging that could transmit sensitive data to a third party. Check the documentation for the Linux distribution used by the AMI for information about improving the security of the system.

To ensure that you don't accidentally lose access to your instance, we recommend that you initiate two SSH sessions and keep the second session open until you've removed credentials that you don't recognize and confirmed that you can still log into your instance using SSH.

1. Identify and disable any unauthorized public SSH keys. The only key in the file should be the key you used to launch the AMI. The following command locates `authorized_keys` files:

   ```
   sudo find / -name "authorized_keys" -print -exec cat {} \;
   ```

2. Disable password-based authentication for the root user. Open the `ssh_config` file and edit the `PermitRootLogin` line as follows:
PermitRootLogin without-password

Alternatively, you can disable the ability to log into the instance as root:

PermitRootLogin No

Then restart the sshd service.

3. Check whether there are any other user accounts that are able to log in to your instance. Accounts with superuser privileges are particularly dangerous. Remove or lock the password of any unknown accounts.

4. Check for open ports that you aren’t using and running network services listening for incoming connections.

5. To prevent preconfigured remote logging, you should delete the existing configuration file and restart the rsyslog service. For example:

```
sudo rm /etc/rsyslog.config
sudo service rsyslog restart
```

6. Verify that all cron jobs are legitimate.

   If you discover a public AMI that you feel presents a security risk, contact the AWS security team. For more information, see the AWS Security Center.

**Making an AMI Public**

Amazon EC2 enables you to share your AMIs with other AWS accounts. You can allow all AWS accounts to launch the AMI (make the AMI public), or only allow a few specific accounts to launch the AMI. You are not billed when your AMI is launched by other AWS accounts; only the accounts launching the AMI are billed.

Before you share an AMI, make sure to read the security considerations in Guidelines for Shared Linux AMIs (p. 61).

**Note**

If an AMI has a product code, you can’t make it public. You must share the AMI with only specific AWS accounts.

**Sharing a Public AMI Using the Console**

To share a public AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. Select your AMI in the list, and then select **Modify Image Permissions** from the Actions list.
4. Select the Public radio button, and then click Save.

**Sharing a Public AMI Using the AWS CLI**

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner’s, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an
AMI, you can make the AMI public (which grants launch permissions to all AWS accounts or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the all group. You can specify both public and explicit launch permissions.

To make an AMI public

Use the `modify-image-attribute` command as follows to add the all group to the launchPermission list for the specified AMI.

```
aws ec2 modify-image-attribute --image-id ami-2bb65342 --launch-permission "{"Add": [{"Group": "all"}]}
```

To verify the launch permissions of the AMI, use the following `describe-image-attribute` command.

```
aws ec2 describe-image-attribute --image-id ami-2bb65342 --attribute launchPermission
```

(Optional) To make the AMI private again, remove the all group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 modify-image-attribute --image-id ami-2bb65342 "{"Remove": [{"Group": "all"}]}
```

Sharing a Public AMI Using the Amazon EC2 CLI

Each AMI has a launchPermission property that controls which AWS accounts, besides the owner’s, are allowed to use that AMI to launch instances. By modifying the launchPermission property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the all group. You can specify both public and explicit launch permissions.

To make an AMI public

Use the `ec2-modify-image-attribute` command as follows to add the all group to the launchPermission list for the specified AMI.

```
ec2-modify-image-attribute ami-2bb65342 --launch-permission -a all
```

To verify the launch permissions of the AMI, use the following command.

```
ec2-describe-image-attribute ami-2bb65342 -l
```

To make the AMI private again, remove the all group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
ec2-modify-image-attribute ami-2bb65342 -l -r all
```
Sharing an AMI with Specific AWS Accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need are the AWS account IDs.

Sharing an AMI Using the Console

To grant explicit launch permissions using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. Select your AMI in the list, and then select Modify Image Permissions from the Actions list.
4. Specify the AWS account number of the user with whom you want to share the AMI in the AWS Account Number field, then click Add Permission.

   To share this AMI with multiple users, repeat the above step until you have added all the required users.
5. To allow create volume permissions for snapshots, check Add "create volume" permissions to the following associated snapshots when creating permissions.

   Note
   You do not need to share the Amazon EBS snapshots than an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch.
6. Click Save when you are done.

Sharing an AMI Using the AWS CLI

Use the modify-image-attribute command to share an AMI as shown in the following examples.

To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account.

```
aws ec2 modify-image-attribute --image-id ami-2bb65342 "{"Add":[{"UserId":"123456789012"}]}
```

To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account:

```
aws ec2 modify-image-attribute --image-id ami-2bb65342 "{"Remove":[{"UserId":"123456789012"}]}
```

To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute --image-id ami-2bb65342 --attribute launchPermission
```
Sharing an AMI Using the Amazon EC2 CLI

Use the `ec2-modify-image-attribute` command to share an AMI as shown in the following examples.

**To grant explicit launch permissions**

The following command grants launch permissions for the specified AMI to the specified AWS account.

```
ec2-modify-image-attribute ami-2bb65342 -l -a 111122223333
```

**To remove launch permissions for an account**

The following command removes launch permissions for the specified AMI from the specified AWS account:

```
ec2-modify-image-attribute ami-2bb65342 -l -r 111122223333
```

**To remove all launch permissions**

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
ec2-reset-image-attribute ami-2bb65342 -l
```

Using Bookmarks

If you have created a public AMI, or shared an AMI with another AWS user, you can create a bookmark that allows a user to access your AMI and launch an instance in their own account immediately. This is an easy way to share AMI references, so users don't have to spend time finding your AMI in order to use it.

Note that your AMI must be public, or you must have shared it with the user to whom you want to send the bookmark.

**To create a bookmark for your AMI**

1. Type a URL with the following information, where `<region>` is the region in which your AMI resides, and `<ami_id>` is the ID of the AMI:

   ```
   ```

   For example, this URL launches an instance from the ami-2bb65342 AMI in the us-east-1 region:

   ```
   ```

2. Distribute the link to users who want to use your AMI.
3. To use a bookmark, click the link or copy and paste it into your browser. The launch wizard opens, with the AMI already selected.
Guidelines for Shared Linux AMIs

If you follow these guidelines, you'll provide a better user experience and make your users' instances less vulnerable to security issues.

Update the AMI Tools at Boot Time

For AMIs backed by instance store, we recommend that your AMIs download and upgrade the Amazon EC2 AMI creation tools during startup. This ensures that new AMIs based on your shared AMIs have the latest AMI tools.

For Amazon Linux, add the following to /etc/rc.local:

```bash
# Update the Amazon EC2 AMI tools
echo " + Updating EC2 AMI tools"
yum update -y aws-amitools-ec2
echo " + Updated EC2 AMI tools"
```

Use this method to automatically update other software on your image.

Note

When deciding which software to automatically update, consider the amount of WAN traffic that the update will generate (your users will be charged for it) and the risk of the update breaking other software on the AMI.

For other distributions, make sure you have the latest AMI tools.

Disable Password-Based Logins for Root

Using a fixed root password for a public AMI is a security risk that can quickly become known. Even relying on users to change the password after the first login opens a small window of opportunity for potential abuse.
To solve this problem, disable password-based logins for the root user. Additionally, we recommend you disable root access.

**To disable password-based logins for root**

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

   ```
   #PermitRootLogin yes
   ```

2. Change the line to:

   ```
   PermitRootLogin without-password
   ```

   The location of this configuration file might differ for your distribution, or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

**Disable Root Access**

When you work with shared AMIs, it is a known best practice to have a secure environment; one of the elements associated with a secure environment is ensuring that the root password is not empty. To do this, log into your running instance and issue the following command to disable root access:

```
[ec2-user ~]$ sudo passwd -l root
```

**Note**

This does not impact the use of `sudo`.

**Remove SSH Host Key Pairs**

If you plan to share an AMI derived from a public AMI, remove the existing SSH host key pairs located in `/etc/ssh`. This forces SSH to generate new unique SSH key pairs when someone launches an instance using your AMI, improving security and reducing the likelihood of "man-in-the-middle" attacks.

The following list shows the SSH files to remove.

- `ssh_host_dsa_key`
- `ssh_host_dsa_key.pub`
- `ssh_host_key`
- `ssh_host_key.pub`
- `ssh_host_rsa_key`
- `ssh_host_rsa_key.pub`

You can securely remove all of these files with the following command.

```
[ec2-user ~]$ sudo shred -u /etc/ssh/*_key /etc/ssh/*_key.pub
```

**Important**

If you forget to remove the existing SSH host key pairs from your public AMI, our routine auditing process notifies you and all customers running instances of your AMI of the potential security risk. After a short grace period, we mark the AMI private.
Install Public Key Credentials

After configuring the AMI to prevent logging in using a password, you must make sure users can log in using another mechanism.

Amazon EC2 allows users to specify a public-private key pair name when launching an instance. When a valid key pair name is provided to the RunInstances API call (or through the command line API tools), the public key (the portion of the key pair that Amazon EC2 retains on the server after a call to CreateKeyPair or ImportKeyPair) is made available to the instance through an HTTP query against the instance metadata.

To log in through SSH, your AMI must retrieve the key value at boot and append it to /root/.ssh/authorized_keys (or the equivalent for any other user account on the AMI). Users can launch instances of your AMI with a key pair and log in without requiring a root password.

Many distributions, including Amazon Linux and Ubuntu, use the cloud-init package to inject public key credentials for a configured user. If your distribution does not support cloud-init, you can add the following code to a system start-up script (such as /etc/rc.local) to pull in the public key you specified at launch for the root user.

```bash
if [ ! -d /root/.ssh ]; then
  mkdir -p /root/.ssh
  chmod 700 /root/.ssh
fi

# Fetch public key using HTTP
if [ $? -eq 0 ]; then
  cat /tmp/my-key >> /root/.ssh/authorized_keys
  chmod 700 /root/.ssh/authorized_keys
  rm /tmp/my-key
fi
```

This can be applied to any user account; you do not need to restrict it to root.

**Note**
Rebundling an instance based on this AMI includes the key with which it was launched. To prevent the key’s inclusion, you must clear out (or delete) the authorized_keys file or exclude this file from rebundling.

Disabling sshd DNS Checks (Optional)

Disabling sshd DNS checks slightly weakens your sshd security. However, if DNS resolution fails, SSH logins still work. If you do not disable sshd checks, DNS resolution failures prevent all logins.

**To disable sshd DNS checks**

1. Open the /etc/ssh/sshd_config file with a text editor and locate the following line:

   ```
   UseDNS yes
   ```

2. Change the line to:

   ```
   UseDNS no
   ```
Note
The location of this configuration file can differ for your distribution or if you are not running
OpenSSH. If this is the case, consult the relevant documentation.

Identify Yourself

Currently, there is no easy way to know who provided a shared AMI, because each AMI is represented
by an account ID.

We recommend that you post a description of your AMI, and the AMI ID, in the Amazon EC2 forum. This
provides a convenient central location for users who are interested in trying new shared AMIs. You can
also post the AMI to the Amazon Machine Images (AMIs) page.

Protect Yourself

The previous sections described how to make your shared AMIs safe, secure, and usable for the users
who launch them. This section describes guidelines to protect yourself from the users of your AMI.

We recommend against storing sensitive data or software on any AMI that you share. Users who launch
a shared AMI might be able to rebundle it and register it as their own. Follow these guidelines to help you
to avoid some easily overlooked security risks:

• Always delete the shell history before bundling. If you attempt more than one bundle upload in the
  same AMI, the shell history contains your secret access key. The following example should be the last
  command executed before bundling from within the instance.

  [ec2-user ~]$ shred -u ~/.history

AWS recommends using the `--exclude directory` option on `ec2-bundle-vol` to skip any directories
and subdirectories that contain secret information that you would not like to include in your bundle. For
more information, see `ec2-bundle-vol` in the Amazon Elastic Compute Cloud Command Line Reference.

• Bundling a running instance requires your private key and X.509 certificate. Put these and other
credentials in a location that is not bundled (such as the instance store).

• Exclude the SSH authorized keys when bundling the image. The Amazon public AMIs store the public
  key used to launch an instance with its SSH authorized keys file.

Note
Unfortunately, it is not possible for this list of guidelines to be exhaustive. Build your shared AMIs
carefully and take time to consider where you might expose sensitive data.

Paid AMIs

A paid AMI is an AMI that you can purchase from a developer.

Amazon EC2 integrates with Amazon DevPay and AWS Marketplace, enabling developers to charge
other Amazon EC2 users for the use of their AMIs or to provide support for instances. For more information
about Amazon DevPay, see the Amazon DevPay site.

The AWS Marketplace is an online store where you can buy software that runs on AWS; including AMIs
that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories,
such as Developer Tools, to enable you to find products to suit your requirements. For more information about AWS Marketplace, see the AWS Marketplace site.

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No additional parameters are required. The instance is charged according to the rates set by the owner of the AMI, as well as the standard usage fees for the related web services; for example, the hourly rate for running a m1.small instance type in Amazon EC2. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

Important
All paid AMIs from Amazon DevPay are backed by instance store. AWS Marketplace supports AMIs backed by Amazon EBS.

Selling Your AMI

You can sell your AMI using either AWS Marketplace or Amazon DevPay. Both help customers buy software that runs on AWS, but AWS Marketplace offers a better shopping experience, making it easier for customers to find your AMI. AWS Marketplace also supports AWS features that Amazon DevPay doesn’t support, such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on AWS Marketplace, see Selling on AWS Marketplace.

For information about how to sell your AMI on Amazon DevPay, see Using DevPay with Your Amazon EC2 AMI.

Finding a Paid AMI

There are several ways that you can find AMIs that are available for you to purchase. For example, you can use AWS Marketplace, the Amazon EC2 console, or the Amazon EC2 CLI. Alternatively, a developer might let you know about a paid AMI themselves.

Finding a Paid AMI Using the Console

To find a paid AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs.
3. Select Public images from the first Filter list, Marketplace images from the second Filter list, and the operating system from the third Filter list.
Finding a Paid AMI Using AWS Marketplace

To find a paid AMI using AWS Marketplace

1. Open AWS Marketplace.
2. Enter the name of the operating system in the search box, and click Go.
3. To scope the results further, use one of the categories or filters.
4. Each product is labeled with its product type: either AMI or Software as a Service.

Finding a Paid Windows AMI Using the AWS CLI

To find a paid Windows AMI using the AWS CLI

You can also find a paid Windows AMI using the describe-images command as follows.

```
ec2-describe-images --owners aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The output from describe-images includes an entry for the product code like the following:

```
"ProductCodes": [
  {
    "ProductCodeId": "product_code",
    "ProductCodeType": "marketplace"
  },
],
```

Finding a Paid Windows AMI Using the Amazon EC2 CLI

To find a paid Windows AMI using the Amazon EC2 CLI

You can also find a paid Windows AMI using the ec2-describe-images command as follows.

```
ec2-describe-images -o aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The following example output from ec2-describe-images includes a product code.

```
IMAGE   ami-a5bf59cc   image_source     123456789012 available public
product_code   x86_64    machine   instance-store
```

Purchase a Paid AMI

You must sign up for (purchase) a paid AMI before you can launch an instance using the AMI.

Typically a seller of a paid AMI presents you with information about the AMI, including its price and a link where you can buy it. When you click the link, you’re first asked to log into AWS, and then you can purchase the AMI.

**Important**

You don’t get the discount from Reserved Instances if you use a paid AMI from Amazon DevPay. That is, if you purchase Reserved Instances, you don’t get the lower price associated with them.
when you launch a paid AMI. You always pay the price that's specified by the seller of the paid AMI.

### Purchasing a Paid AMI Using the Console

You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see Launching an AWS Marketplace Instance (p. 306).

### Subscribing to a Product Using AWS Marketplace

To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be subscribed to the product from which to launch the instance. There are two ways to subscribe to products in the AWS Marketplace:

- **AWS Marketplace website**: You can launch preconfigured software quickly with the 1-Click deployment feature.
- **Amazon EC2 launch wizard**: You can search for an AMI and launch an instance directly from the wizard. For more information, see Launching an AWS Marketplace Instance (p. 306).

### Purchasing a Paid AMI From a Developer

The developer of a paid AMI can enable you to purchase a paid AMI that isn't listed in AWS Marketplace. The developer provides you with a link that enables you to purchase the product through Amazon. You can sign in with your Amazon.com credentials and select a credit card that's stored in your Amazon.com account to use when purchasing the AMI.

### Getting the Product Code for Your Instance

You can determine whether your instance has an Amazon DevPay or AWS Marketplace product code using its instance metadata. For more information about retrieving metadata, see Instance Metadata and User Data (p. 268).

To retrieve a product code, use the following query:

```
```

If the instance has a product code, Amazon EC2 returns it. For example:

```
774F4FF8
```

### Using Paid Support

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

**Important**

You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.
To associate a product code with your AMI, use one of the following commands, where \textit{ami\_id} is the ID of the AMI and \textit{product\_code} is the product code:

- \texttt{modify-image-attribute} (AWS CLI)
  \begin{verbatim}
  aws ec2 modify-image-attribute --image-id \textit{ami\_id} --product-codes "\textit{product\_code}"
  \end{verbatim}

- \texttt{ec2-modify-image-attribute} (Amazon EC2 CLI)
  \begin{verbatim}
  ec2-modify-image-attribute \textit{ami\_id} --product-code \textit{product\_code}
  \end{verbatim}

After you set the product code attribute, it cannot be changed or removed.

**Bills for Paid and Supported AMIs**

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see Paying For AWS Marketplace Products.

**Managing Your AWS Marketplace Subscriptions**

On the AWS Marketplace website, you can check your subscription details, view the vendor’s usage instructions, manage your subscriptions, and more.

**To check your subscription details**

1. Log in to the AWS Marketplace.
2. Click \textit{Your Account}.
3. Click \textit{Manage Your Software Subscriptions}.
4. All your current subscriptions are listed. Click \textit{Usage Instructions} to view specific instructions for using the product, for example, a user name for connecting to your running instance.

**To cancel an AWS Marketplace subscription**

1. Ensure that you have terminated any instances running from the subscription.
   a. Open the Amazon EC2 console.
   b. In the navigation pane, click \textit{Instances}.
   c. Select the instance, and select \textit{Terminate} from the \textit{Actions} menu. When prompted, click \textit{Yes}, \textit{Terminate}.
2. Log in to the AWS Marketplace, and click \textit{Your Account}, then \textit{Manage Your Software Subscriptions}.
3. Click \textit{Cancel subscription}. You are prompted to confirm your cancellation.

**Note**

After you’ve canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.
Creating an Amazon EBS-Backed Linux AMI

To create an Amazon EBS-backed Linux AMI, start from an instance that you've launched from an existing Amazon EBS-backed Linux AMI. After you've customized the instance to suit your needs, create and register a new AMI, which you can use to launch new instances with these customizations.

If you need to create an Amazon EBS-backed Windows AMI, see Creating an Amazon EBS-Backed Windows AMI in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

The AMI creation process is different for instance store-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see Storage for the Root Device (p. 50). If you need to create an instance store-backed Linux AMI, see Creating an Instance Store-Backed Linux AMI (p. 72).

• Creating the AMI from an Instance (p. 70)
• Creating an AMI from a Snapshot (p. 71)

Overview of the Creation Process for Amazon EBS-Backed AMIs

The following diagram summarizes the creation process for Amazon EBS-backed AMIs.

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, it's best to stop the instance before you create an AMI to ensure data integrity. Then, you can create the image. When you create an Amazon EBS-backed AMI, we automatically register it for you.

Amazon EC2 powers down the instance before creating the AMI to ensure that everything on the instance is stopped and in a consistent state during the creation process. If you're confident that your instance is in a consistent state appropriate for AMI creation, you can tell Amazon EC2 not to power down and reboot the instance. Some file systems, such as xfs, can freeze and unfreeze activity, making it safe to create the image without rebooting the instance.

During the AMI creation process, Amazon EC2 creates snapshots of your instance's root volume and any other Amazon EBS volumes attached to your instance. Depending on the size of the volumes, it may take several minutes for the entire AMI creation process to complete (sometimes up to 24 hours). To help speed up this process, we recommend that you create snapshots of your volumes immediately before creating an AMI. For more information, see Creating an Amazon EBS Snapshot (p. 559).

After the process completes, you have a new AMI and snapshot created from the root volume of the instance. When you launch an instance using the new AMI, we create a new Amazon EBS volume for its root volume using the snapshot. Both the AMI and the snapshot incur charges to your account until you delete them. For more information, see Deregistering Your AMI (p. 83).
If you add instance-store volumes or Amazon EBS volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. The instance-store volumes specified in the block device mapping for the new instance are new and don't contain any data from the instance store volumes of the instance you used to create the AMI. The data on Amazon EBS volumes persists. For more information, see Block Device Mapping (p. 592).

Creating the AMI from an Instance

You can create an AMI using the AWS Management Console or the command line.

To create an AMI from an instance using the console

1. Open the Amazon EC2 console.
2. If you don't have a running instance that uses an Amazon EBS volume for the root device, you must launch one. For instructions, see Launching an Instance (p. 300).
3. (Optional) Connect to the instance and customize it. For example, you can install software and applications, copy data, or attach additional Amazon EBS volumes. For more information about connecting to an instance, see Connect to Your Instance (p. 308).
4. (Optional) Create snapshots of all the volumes attached your instance. This may help reduce the time it takes to create the AMI. For more information about creating snapshots, see Creating an Amazon EBS Snapshot (p. 559).
5. In the navigation pane, click Instances and select your instance. Click Actions and then click Create Image.
   
   Tip
   
   If this option is disabled, your instance isn't an Amazon EBS-backed instance.

6. In the Create Image dialog box, specify the following, and then click Create Image.
   
   a. A unique name for the image.
   b. (Optional) A description of the image, up to 255 characters.
   c. By default, Amazon EC2 shuts down the instance, takes snapshots of any attached volumes, creates and registers the AMI, and then reboots the instance. Select No reboot if you don't want your instance to be shut down.
      
      Warning
      
      If you select No reboot, we can't guarantee the file system integrity of the created image.
   d. (Optional) You can modify the root volume, Amazon EBS volumes, and instance store volumes as follows:
      
      • To change the size of the root volume, locate the Root volume in the Type column, and fill in the Size field.
      • To suppress an Amazon EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the EBS volume in the list and click Delete.
      • To add an Amazon EBS volume, click Add New Volume, select EBS from the Type list, and fill in the fields. When you then launch an instance from your new AMI, these additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.
      • To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume in the list and click Delete.
      • To add an instance store volume, click Add New Volume, select Instance Store from the Type list, and select a device name from the Device list. When you launch an instance from your new AMI, these additional volumes are automatically initialized and mounted. These
volumes don't contain data from the instance store volumes of the running instance from which you based your AMI.

7. Click AMIs in the navigation pane to view the status of your AMI. While the new AMI is being created, its status is pending. This process typically takes a few minutes to finish, and then the status of your AMI is available.

8. (Optional) Click Snapshots in the navigation pane to view the snapshot that was created for the new AMI. When you launch an instance from this AMI, we use this snapshot to create its root device volume.

To create an AMI from an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- create-image (AWS CLI)
- ec2-create-image (Amazon EC2 CLI)
- New-EC2Image (AWS Tools for Windows PowerShell)

Creating an AMI from a Snapshot

If you have a snapshot of the root device volume of an instance, you can create an AMI from this snapshot using the AWS Management Console or the command line.

To create an AMI from a snapshot using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, under Elastic Block Store, click Snapshots.
3. Select the snapshot, and then select Create Image from the Actions list.
4. In the Create Image from EBS Snapshot dialog box, do the following:
   a. Select the architecture from the Architecture list (i386 for 32-bit or x86_64 for 64-bit).
   b. Select the AKI from the Kernel ID list. If you select the default AKI or don't select an AKI, you'll be required to specify an AKI every time you launch an instance using this AMI. In addition, your instance may fail the health checks if the default AKI is incompatible with the instance.
   c. Click Create.

To create an AMI from a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- register-image (AWS CLI)
- ec2-register (Amazon EC2 CLI)
- Register-EC2Image (AWS Tools for Windows PowerShell)
Creating an Instance Store-Backed Linux AMI

To create an instance store-backed Linux AMI, start from an instance that you've launched from an existing instance store-backed Linux AMI. After you've customized the instance to suit your needs, bundle the volume and register a new AMI, which you can use to launch new instances with these customizations.

If you need to create an instance store-backed Windows AMI, see Creating an Instance Store-Backed Windows AMI in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

The AMI creation process is different for instance store-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see Storage for the Root Device (p. 50). If you need to create an Amazon EBS-backed Linux AMI, see Creating an Amazon EBS-Backed Linux AMI (p. 69).

Overview of the Creation Process for Instance Store-Backed AMIs

The following diagram summarizes the process of creating an AMI from an instance store-backed instance.

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, you can bundle it. It takes several minutes for the bundling process to complete. After the process completes, you have a bundle, which consists of an image manifest (image.manifest.xml) and files (image.part.xx) that contain a template for the root volume. Next you upload the bundle to your Amazon S3 bucket and then register your AMI.

When you launch an instance using the new AMI, we create the root volume for the instance using the bundle that you uploaded to Amazon S3. The storage space used by the bundle in Amazon S3 incurs charges to your account until you delete it. For more information, see Deregistering Your AMI (p. 83).

If you add instance store volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. For more information, see Block Device Mapping (p. 592).
Prerequisites

Before you can create the AMI, you must complete the following tasks:

- Install the AMI tools. For more information, see Set Up the AMI Tools.
- Install the API tools. For more information, see Setting Up the Amazon EC2 Command Line Interface Tools on Linux.
- Ensure that you have an Amazon S3 bucket for the bundle. To create an Amazon S3 bucket, open the Amazon S3 console and click Create Bucket.

  **Note**
  
  You can also use the AWS CLI mb command to create a bucket. To get started with the AWS CLI, see AWS Command Line Interface User Guide.

- Ensure that you have the following credentials:
  - Your AWS account ID. To retrieve your account ID, go to Your Security Credentials and expand Account Identifiers.
  - An X.509 certificate and private key. If you need to create an X.509 certificate, go to Your Security Credentials, expand X.509 Certificates, and click Create New Certificate. The X.509 certificate and private key are used to encrypt and decrypt your AMI.
  - Your access key ID. If you need to retrieve or create an access key ID, go to Your Security Credentials, and expand Access Keys.
  - Your secret access key. You can't retrieve your secret access key. Therefore, if you can't find your secret access key, you'll need to create a new one. To create a secret access key, go to Your Security Credentials, expand Access Keys, and click Create New Access Key.
  - Connect to your instance and customize it. For example, you can install software and applications, copy data, delete temporary files, and modify the Linux configuration.

Creating an AMI from an Instance Store-Backed Linux Instance

To prepare to use the Amazon EC2 AMI Tools (HVM instances only)

The Amazon EC2 AMI tools require GRUB Legacy to boot properly. Some AMIs (most notably, Ubuntu) are configured to use GRUB 2. You must check to see that your instance uses GRUB Legacy, and if not, you need to install and configure it.

HVM instances also require partitioning tools to be installed for the AMI tools to work properly.

1. Check to see if your instance uses GRUB Legacy.

   a. List the block devices to find the root block device.

   ```bash
   [ec2-user ~]$ lsblk
   NAME     MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
   xvda      202:0   0   8G  0 disk
   xvda1 202:1   0   8G  0 part /
   xvdb      202:16   0  30G  0 disk /media/ephemeral0
   ```

   In this example, the root device (indicated by a MOUNTPOINT of /) is `/dev/xvda`. The root block device is its parent, `/dev/xvda`.

   b. Determine the GRUB version on the root block device.
In the above example, the GRUB version is 0.94, which is GRUB Legacy. If your GRUB version is 0.9x or less, you may move on to Step 3 (p. 74). If you do not see a GRUB version in this output, try the `grub-install -v` command.

```
ubuntu:~$ grub-install -v
grub-install (GRUB) 1.99-2ubuntu3.10
```

In this example, the GRUB version is greater than 0.9x, so GRUB Legacy must be installed. Proceed to Step 2 (p. 74).

2. Install the grub package using the package manager for your distribution to install GRUB Legacy. For Ubuntu instances, use the following command.

```
ubuntu:~$ sudo apt-get install -y grub
```

You can verify that your instance is using GRUB Legacy with the `grub --version` command.

```
ubuntu:~$ grub --version
grub (GNU GRUB 0.97)
```

3. Install the following partition management packages using the package manager for your distribution.

- `gdisk` (some distributions may call this package `gptfdisk` instead)
- `kpartx`

For Ubuntu instances, use the following command.

```
ubuntu:~$ sudo apt-get install -y gdisk kpartx
```

4. Check the kernel parameters for your instance.

```
ubuntu:~$ cat /proc/cmdline
BOOT_IMAGE=/boot/vmlinuz-3.2.0-54-virtual root=UUID=4f392932-ed93-4f8f-aee7-72bc5bb6ca9d ro console=ttyS0 xen_emul_unplug=unnecessary
```

Note the options following the kernel and root device parameters, `console=ttyS0` and `xen_emul_unplug=unnecessary`.

5. Check the kernel entries in `/boot/grub/menu.lst`.

```
ubuntu:~$ grep \^kernel /boot/grub/menu.lst
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=hvc0
```
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
kernel /boot/memtest86+.bin

Note that the console parameter is pointing to hvc0 instead of ttyS0 and that the xen_emul_unplug=unnecessary parameter is missing.

6. Edit the /boot/grub/menu.lst file with your favorite text editor (such as vim or nano) to change the console and add the parameters you identified earlier to the boot entries.

```
title           Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual
root            (hd0)
kern**el** /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs
ro console=ttyS0 xen_emul_unplug=unnecessary
initrd          /boot/initrd.img-3.2.0-54-virtual

```

```
title           Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual (recovery mode)
root            (hd0)
kern**el** /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs
ro single console=ttyS0 xen_emul_unplug=unnecessary
initrd          /boot/initrd.img-3.2.0-54-virtual

```

```
title           Ubuntu 12.04.3 LTS, memtest86+
root            (hd0)
kern**el** /boot/memtest86+.bin
```

7. Verify that your kernel entries now contain the correct parameters.

```
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro con
sole=ttyS0 xen_emul_unplug=unnecessary
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
console=ttyS0 xen_emul_unplug=unnecessary
kernel /boot/memtest86+.bin
```

To create an AMI from an instance store-backed Linux instance

This procedure assumes that you have satisfied the prerequisites in Prerequisites (p. 73).

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.

   a. Create a temporary directory on your instance for your credentials as follows:

   ```
   [ec2-user ~]$ mkdir /tmp/cert
   ```

   This enables you to exclude your credentials from the created image.

   b. Copy your X.509 certificate and private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as scp (p. 310). The -i my-private-key.pem option in the following scp command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

   ```
you@your_computer:~ $ scp -i my-private-key.pem /path/to/pk-HKZYKTAIG2ECMXYIBJ3HXV4ZBEXAMPLE.pem /path/to/cert-HKZYKTAIG2ECMXY
   ```
2. Prepare the bundle to upload to Amazon S3 using the `ec2-bundle-vol` command. Be sure to specify the `--e` option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include `.sw`, `.swo`, `.swp`, `.pem`, `.priv`, `.id_rsa`, `.id_dsa`, `.gpg`, `.jks`, `.ssh/authorized_keys`, and `.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

**Important**

By default, the AMI bundling process creates a compressed, encrypted collection of files in the `/tmp` directory that represent your root volume. If you do not have enough free disk space in `/tmp` to store the bundle, you need to specify a different location for the bundle to be stored with the `--d /path/to/bundle/storage` option. Some instances have ephemeral storage mounted at `/mnt` or `/media/ephemeral0` that you can use, or you can also create (p. 526), attach (p. 529), and mount (p. 532) a new Amazon EBS volume to store the bundle.

a. The `ec2-bundle-vol` command needs to run as `root`. For most commands, you can use `sudo` to gain elevated permissions, but in this case, you should run `sudo -E su` to keep your environment variables.

```
[ec2-user ~]$ sudo -E su
```

b. Run the `ec2-bundle-vol` command with the following arguments. If you do not have enough available disk space in `/tmp` to store your bundle, specify a location that has available space with the `--d /path/to/bundle/storage` option. For HVM instances, be sure to add the `--partition` flag; otherwise, your AMI will not boot. For more information on this command and its available options, see `ec2-bundle-vol` in the Amazon Elastic Compute Cloud Command Line Reference.

```
[root ec2-user]$ $EC2_AMITOOL_HOME/bin/ec2-bundle-vol -k /tmp/cert/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u your_aws_account_id --x86_64 --e /tmp/cert
```

It can take a few minutes to create the image. When this command completes, your `/tmp` directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

c. Exit from the `root` shell.

```
[root ec2-user]$ exit
```

3. Upload your bundle to Amazon S3 using the `ec2-upload-bundle` command. Note that if the bundle prefixes (directories) don’t exist in the bucket, this command creates them.

**Note**

If you specified a path with the `--d /path/to/bundle/storage` option in Step 2.b (p. 76), use that same path in the `--m` option below, instead of `/tmp`.
Converting your Instance Store-Backed AMI to an
Amazon EBS-Backed AMI

You can convert an instance store-backed Linux AMI that you own to an Amazon EBS-backed Linux AMI.

Important
You can’t convert an instance store-backed Windows AMI to an Amazon EBS-backed Windows AMI and you cannot convert an AMI that you do not own.

To convert an instance store-backed AMI to an Amazon EBS-backed AMI

1. Launch an Amazon Linux instance from an Amazon EBS-backed AMI. For more information, see Launching an Instance (p. 300). Amazon Linux instances have the Amazon EC2 command line and AMI tools pre-installed.
2. Upload the X.509 private key that you used to bundle your instance store-backed AMI to your instance. We use this key to ensure that only you and Amazon EC2 can access your AMI.
   a. Create a temporary directory on your instance for your X.509 private key as follows:

   ```
   [ec2-user ~]$ mkdir /tmp/cert
   ```

   b. Copy your X.509 private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as scp (p. 310). The `my-private-key` parameter in the following command is the private key you use to connect to your instance with SSH. For example:

   ```
   you@your_computer:~ $ scp -i my-private-key.pem /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-user@ec2-203-0-113-25.compute-
3. Set environment variables for your AWS access key and secret key.

```
[ec2-user ~]$ export AWS_ACCESS_KEY=your_access_key_id
[ec2-user ~]$ export AWS_SECRET_KEY=your_secret_access_key
```

4. Prepare an Amazon EBS volume for your new AMI.

   a. Create an empty Amazon EBS volume in the same Availability Zone as your instance using the `ec2-create-volume` command. Note the volume ID in the command output.

   **Important**
   This Amazon EBS volume must be the same size or larger than the original instance store root volume.

```
[ec2-user ~]$ ec2-create-volume --size 10 --region us-west-2 --availability-zone us-west-2b
VOLUME volume_id 10  us-west-2b creating 2014-01-24T23:11:45+0000
```

   b. Attach the volume to your Amazon EBS-backed instance using the `ec2-attach-volume` command.

```
[ec2-user ~]$ ec2-attach-volume volume_id -i instance_id --device /dev/sdb
ATTACHMENT volume_id  instance_id /dev/sdb attaching 2014-01-24T23:15:34+0000
```

5. Create a folder for your bundle.

```
[ec2-user ~]$ mkdir /tmp/bundle
```

6. Download the bundle for your instance store-based AMI to `/tmp/bundle` using the `ec2-download-bundle` command.

```
[ec2-user ~]$ ec2-download-bundle -b my-s3-bucket/bundle_folder/bundle_name
-m image.manifest.xml -a $AWS_ACCESS_KEY -s $AWS_SECRET_KEY
--privatekey /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -d /tmp/bundle
```

7. Reconstitute the image file from the bundle using the `ec2-unbundle` command.

   a. Change directories to the bundle folder.

```
[ec2-user ~]$ cd /tmp/bundle/
```

   b. Run the `ec2-unbundle` command.
8. Copy the files from the unbundled image to the new Amazon EBS volume.

```
[ec2-user bundle]$ sudo dd if=/tmp/bundle/image of=/dev/sdb bs=1M
```

9. Create a mount point for the new Amazon EBS volume and mount the volume.

```
[ec2-user bundle]$ sudo mkdir /mnt/ebs
[ec2-user bundle]$ sudo mount /dev/sdb /mnt/ebs
```

10. Open the `/etc/fstab` file on the EBS volume with your favorite text editor (such as `vim` or `nano`) and remove any entries for instance store (ephemeral) volumes. Because the Amazon EBS volume is mounted on `/mnt/ebs`, the `fstab` file is located at `/mnt/ebs/etc/fstab`.

```
[ec2-user bundle]$ sudo nano /mnt/ebs/etc/fstab

#  
LABEL=/     /           ext4    defaults,noatime  1   1  
tmpfs   /dev/shm    tmpfs   defaults               0   0  
devpts  /dev/pts    devpts  gid=5,mode=620     0   0  
sysfs   /sys        sysfs   defaults               0   0  
proc    /proc       proc    defaults               0   0  
/dev/sdb        /media/ephemeral0       auto    defaults,comment=cloudconfig  0   2  
```

In the above example, the last line should be removed.

11. Unmount the volume and detach it from the instance.

```
[ec2-user bundle]$ sudo umount /mnt/ebs
[ec2-user bundle]$ ec2-detach-volume volume_id --region us-west-2
ATTACHMENT volume_id instance_id /dev/sdb detaching 2014-01-24T23:15:34+0000
```

12. Create an AMI from the new Amazon EBS volume as follows.

   a. Create a snapshot of the new Amazon EBS volume.

```
[ec2-user bundle]$ ec2-create-snapshot --region us-west-2 -d "your_snapshot_description" -O $AWS_ACCESS_KEY -W $AWS_SECRET_KEY volume_id
SNAPSHOT snapshot_id volume_id pending 2014-01-25T00:18:48+0000 1234567891011 10 your_snapshot_description
```

   b. Check to see that your snapshot is complete.

```
[ec2-user bundle]$ ec2-describe-snapshots --region us-west-2 snapshot_id
SNAPSHOT snapshot_id volume_id completed 2014-01-25T00:18:48+0000 100% 1234567891011 10 your_snapshot_description
```
c. Identify the architecture and the kernel image (aki) used on the original AMI with the `ec2-describe-images` command. You need the AMI ID of the original instance store-backed AMI for this step.

```
[ec2-user bundle]$ ec2-describe-images --region us-west-2 ami-id
```

In this example, the architecture is x86_64 and the kernel image ID is aki-fc8f11cc. Use these values in the following step. If the output of the above command also lists an ari ID, take note of that as well.

d. Register your new AMI with the snapshot ID of your new Amazon EBS volume and the values from the previous step. If the previous command output listed an ari ID, include that in the following command with `--ramdisk ari_id`.

```
[ec2-user bundle]$ ec2-register --region us-west-2 -n your_new_ami_name -s snapshot_id -a x86_64 --kernel aki-fc8f11cc
```

13. (Optional) After you have tested that you can launch an instance from your new AMI, you can delete the Amazon EBS volume that you created for this procedure.

```
$ ec2-delete-volume volume_id
```

Copying an AMI

You can easily copy the Amazon Machine Images (AMIs) that you own to other AWS regions and scale your applications to take advantage of AWS's geographically diverse regions.

Copying your AMIs provides the following benefits:

- Consistent global deployment: You can copy an AMI from one region to another, enabling you to launch consistent instances based from the same AMI into different regions.
- Scalability: You can more easily design and build world-scale applications that meet the needs of your users, regardless of their location.
- Performance: You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of region-specific features, such as instance types or other AWS services.
- High availability: You can design and deploy applications across AWS regions, to increase availability.

AMI Copy

You can copy both Amazon EBS-backed AMIs and instance-store-backed AMIs. You can copy an AMI to as many regions as you like. You can also copy an AMI to the same region. Each copy of an AMI results in a new AMI with its own unique AMI ID. When you launch an instance from an AMI, we launch it into the same region as the AMI you select, as shown in the following diagram.
When you copy an AMI, the new AMI is fully independent of the source AMI; there is no link to the original (source) AMI. You can modify the new AMI without affecting the source AMI. The reverse is also true: you can modify the source AMI without affecting the new AMI. Therefore, if you make changes to the source AMI and want those changes to be reflected in the AMI in the destination region, you must recopy the source AMI to the destination region.

We don’t copy launch permissions, user-defined tags, or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions, user-defined tags, and Amazon S3 bucket permissions to the new AMI.

We try to find matching AKIs and ARIs for the new AMI in the destination region. If we can’t find a matching AKI or ARI, then we don’t copy the AMI. If you are using the AKIs and ARIs that we recommend, the copy operation registers the AMI with the appropriate AKI and ARI in the destination region. If you get an error message “Failed to find matching AKI/ARI”, it means that the destination region doesn’t contain an AKI or ARI that matches those specified in the source AMI. If your AMI uses a PV-GRUB AKI, then you can update the AMI to leverage the latest version of PV-GRUB. For more information on PV-GRUB and AKIs, see Using Your Own Linux Kernels (p. 91).

There are no charges for copying an AMI. However, standard storage and data transfer rates apply.

**Copying an Amazon EC2 AMI**

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination region may still use the resources from the source region, which can impact performance and cost.

You can copy an AMI using the AWS Management Console or the command line.

**To copy an AMI using the console**

1. Open the Amazon EC2 console.
2. From the navigation bar, select the region that contains the AMI to copy.
3. In the navigation pane, click AMIs.
4. Select the AMI to copy, click Actions, and then click Copy AMI.
5. In the AMI Copy page, set the following fields, and then click Copy AMI:
   - **Destination region**: Select the region to which you want to copy the AMI.
   - **Name**: Specify a name for the new AMI.
   - **Description**: By default, the description includes information about the source AMI so that you can identify a copy from the original. You can change this description as necessary.
6. We display a confirmation page to let you know that the copy operation has been initiated and provide you with the ID of the new AMI.

To check on the progress of the copy operation immediately, click the provided link to switch to the destination region. To check on the progress later, click Done, and then when you are ready, use the navigation pane to switch to the destination region.

The initial status of the destination AMI is pending and the operation is complete when the status is available.

To copy an AMI using the command line

Copying an AMI from the command line requires that you specify both the source and destination regions. You specify the source region using the --source-region parameter. For the destination region, you have two options:

- Use the --region parameter.
- Set an environmental variable. For more information, see Setting up the CLI Tools (Linux) and Setting up the CLI Tools (Windows).

You can copy an AMI using one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- copy-image (AWS CLI)
- ec2-copy-image (Amazon EC2 CLI)
- Copy-EC2Image (AWS Tools for Windows PowerShell)

Stopping a Pending AMI Copy Operation

You can stop a pending AMI copy using the AWS Management Console or the command line.

To stop an AMI copy operation using the console

1. Open the Amazon EC2 console.
2. From the navigation bar, select the destination region from the region selector.
3. In the navigation pane, click AMIs.
4. Select the AMI you want to stop copying, click Actions, and then click Deregister.
5. When asked for confirmation, click Continue.

To stop an AMI copy operation using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- deregister-image (AWS CLI)
- ec2-deregister (Amazon EC2 CLI)
- Unregister-EC2Image (AWS Tools for Windows PowerShell)
Deregistering Your AMI

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances.

When you deregister an AMI, it doesn't affect any instances that you've already launched from the AMI. You'll continue to incur usage costs for these instances. Therefore, if you are finished with these instances, you should terminate them.

The procedure that you'll use to clean up your AMI depends on whether it is backed by Amazon EBS or instance store.

- Cleaning Up Your Instance Store-Backed AMI (p. 84)

Cleaning Up Your Amazon EBS-Backed AMI

When you deregister an Amazon EBS-backed AMI, it doesn't affect the snapshot that we created when you created the AMI. You'll continue to incur usage costs for this snapshot in Amazon EBS. Therefore, if you are finished with the snapshot, you should delete it.

The following diagram illustrates the process for cleaning up your Amazon EBS-backed AMI.

To clean up your Amazon EBS-backed AMI

1. Open the Amazon EC2 console.
2. In the navigation pane, click AMIs. Select the AMI, click Actions, and then click Deregister. When prompted for confirmation, click Continue.

   The AMI status is now unavailable.

3. In the navigation pane, click Snapshots. Select the snapshot and click Delete Snapshot. When prompted for confirmation, click Yes, Delete.

4. (Optional) If you are finished with an instance that you launched from the AMI, terminate it. In the navigation pane, click Instances. Select the instance, click Actions, and then click Terminate. When prompted for confirmation, click Yes, Terminate.
Cleaning Up Your Instance Store-Backed AMI

When you deregister an instance store-backed AMI, it doesn't affect the files that you uploaded to Amazon S3 when you created the AMI. You'll continue to incur usage costs for these files in Amazon S3. Therefore, if you are finished with these files, you should delete them.

The following diagram illustrates the process for cleaning up your instance store-backed AMI.

To clean up your instance store-backed AMI

1. Deregister the AMI using the `ec2-deregister` command as follows.

   ```bash
   ec2-deregister ami_id
   ```

   The AMI status is now unavailable.

2. Delete the bundle using the `ec2-delete-bundle` command as follows.

   ```bash
   ec2-delete-bundle -b myawsbucket/myami -a your_access_key_id -s your_secret_access_key -p image
   ```

3. (Optional) If you are finished with an instance that you launched from the AMI, you can terminate it using the `ec2-terminate-instances` command as follows.

   ```bash
   ec2-terminate-instances instance_id
   ```

4. (Optional) If you are finished with the Amazon S3 bucket that you uploaded the bundle to, you can delete the bucket. To delete an Amazon S3 bucket, open the Amazon S3 console, select the bucket, click Actions, and then click Delete.

Amazon Linux

Amazon Linux is provided by Amazon Web Services (AWS). It is designed to provide a stable, secure, and high-performance execution environment for applications running on Amazon EC2. It also includes packages that enable easy integration with AWS, including launch configuration tools and many popular AWS libraries and tools. AWS provides ongoing security and maintenance updates to all instances running Amazon Linux.
To launch an Amazon Linux instance, use an Amazon Linux AMI. AWS provides Amazon Linux AMIs to Amazon EC2 users at no additional cost.

**Finding the Amazon Linux AMI**

For a list of the latest Amazon Linux AMIs, see Amazon Linux AMIs.

**Launching and Connecting to an Amazon Linux Instance**

After locating your desired AMI, note the AMI ID. You can use the AMI ID to launch and then connect to your instance.

Amazon Linux does not allow remote root SSH by default. Also, password authentication is disabled to prevent brute-force password attacks. To enable SSH logins to an Amazon Linux instance, you must provide your key pair to the instance at launch. You must also set the security group used to launch your instance to allow SSH access. By default, the only account that can log in remotely using SSH is `ec2-user`; this account also has `sudo` privileges. If you want to enable remote root log in, please be aware that it is less secure than relying on key pairs and a secondary user.

For information about launching and using your Amazon Linux instance, see Launch Your Instance (p. 300). For information about connecting to your Amazon Linux instance, see Connecting to Your Linux/Unix Instance (p. 309).

**Identifying Amazon Linux AMI Images**

Each image contains a unique `/etc/image-id` that identifies the AMI. This file contains information about the image.

The following is an example of the `/etc/image-id` file:

```
[ec2-user ~]$ cat /etc/image-id
image_name="amzn-ami-pv"
image_version="2014.03"
image_arch="x86_64"
```

API Version 2014-02-01
85
The image_name, image_version, and image_arch items come from the build recipe that Amazon used to construct the image. The image_stamp is simply a unique random hex value generated during image creation. The image_date item is in YYYYMMDDhhmms format, and is the UTC time of image creation. The recipe_name and recipe_id refer to the name and ID of the build recipe Amazon used to construct the image, which identifies the current running version of Amazon Linux. This file will not change as you install updates from the yum repository.

Amazon Linux contains an /etc/system-release file that specifies the current release that is installed. This file is updated through yum and is part of the system-release RPM.

The following is an example of an /etc/system-release file:

```
[ec2-user ~]$ cat /etc/system-release
Amazon Linux AMI release 2014.03
```

Amazon Linux also contains a machine readable version of the /etc/system-release file found in /etc/system-release-cpe and follows the CPE specification from MITRE (CPE).

## Included AWS Command Line Tools

The following popular command line tools for AWS integration and usage have been included in Amazon Linux or in the default repositories:

- aws-amitools-ec2
- aws-apitools-as
- aws-apitools-cfn
- aws-apitools-common
- aws-apitools-ec2
- aws-apitools-elb
- aws-apitools-iam
- aws-apitools-mon
- aws-apitools-rds
- aws-cfn-bootstrap
- aws-cli
- aws-scripts-ses

To simplify the configuration of these tools, a simple script has been included to prepare AWS_CREDENTIAL_FILE, JAVA_HOME, AWS_PATH, PATH, and product-specific environment variables after a credential file has been installed.

Also, to allow the installation of multiple versions of the API and AMI tools, we have placed symbolic links to the desired versions of these tools in /opt/aws, as described here:

```
/opt/aws/bin
```

Symbolic links to /bin directories in each of the installed tools directories.
Products are installed in directories of the form `name-version` and a symbolic link `name` that is attached to the most recently installed version.

`/opt/aws/{apitools|amitools}/name/environment.sh`

Used by `/etc/profile.d/aws-apitools-common.sh` to set product-specific environment variables, such as `EC2_HOME`.

**cloud-init**

The `cloud-init` package is an open source application built by Canonical that is used to bootstrap Linux images in a cloud computing environment, such as Amazon EC2. Amazon Linux contains a customized version of `cloud-init`. It enables you to specify actions that should happen to your instance at boot time. You can pass desired actions to `cloud-init` through the user data fields when launching an instance. This means you can use common AMIs for many use cases and configure them dynamically at startup. Amazon Linux also uses `cloud-init` to perform initial configuration of the `ec2-user` account.

For more information about `cloud-init`, see [https://help.ubuntu.com/community/CloudInit](https://help.ubuntu.com/community/CloudInit).

Amazon Linux uses the following `cloud-init` actions (configurable in `/etc/sysconfig/cloudinit`):

- **action:** `INIT` (always runs)
  - Sets a default locale
  - Sets the hostname
  - Parses and handles user data
- **action:** `CONFIG_SSH`
  - Generates host private SSH keys
  - Adds a user's public SSH keys to `.ssh/authorized_keys` for easy login and administration
- **action:** `PACKAGE_SETUP`
  - Prepares `yum` repo
  - Handles package actions defined in user data
- **action:** `RUNCMD`
  - Runs a shell command
- **action:** `RUN_USER_SCRIPTS`
  - Executes user scripts found in user data
- **action:** `CONFIG_MOUNTS`
  - Mounts ephemeral drives
- **action:** `CONFIG_LOCALE`
  - Sets the locale in the locale configuration file according to user data

---

**Supported User-Data Formats**

The `cloud-init` package supports user-data handling of a variety of formats:

- Gzip
  - If user-data is gzip compressed, `cloud-init` decompresses the data and handles it appropriately.
- MIME multipart
  - Using a MIME multipart file, you can specify more than one type of data. For example, you could specify both a user-data script and a cloud-config type. Each part of the multipart file can be handled by `cloud-init` if it is one of the supported formats.
- Base64 decoding
• If user-data is base64-encoded, cloud-init determines if it can understand the decoded data as one of the supported types. If it understands the decoded data, it decodes the data and handles it appropriately. If not, it returns the base64 data intact.

• User-Data script
  • Begins with #! or Content-Type: text/x-shellscript.
  • The script is executed by /etc/init.d/cloud-init-user-scripts during the first boot cycle. This occurs late in the boot process (after the initial configuration actions are performed).

• Include file
  • Begins with #include or Content-Type: text/x-include-url.
  • This content is an include file. The file contains a list of URLs, one per line. Each of the URLs is read, and their content passed through this same set of rules. The content read from the URL can be gzipped, MIME-multi-part, or plain text.

• Cloud Config Data
  • Begins with #cloud-config or Content-Type: text/cloud-config.
  • This content is cloud-config data. See the examples for a commented example of supported configuration formats.

• Cloud Boothook
  • Begins with #cloud-boothook or Content-Type: text/cloud-boothook.
  • This content is boothook data. It is stored in a file under /var/lib/cloud and then executed immediately.
  • This is the earliest "hook" available. Note that there is no mechanism provided for running it only one time. The boothook must take care of this itself. It is provided with the instance ID in the environment variable INSTANCE_ID. Use this variable to provide a once-per-instance set of boothook data.

## Repository Configuration

Beginning with the 2011.09 release of Amazon Linux, Amazon Linux AMIs are treated as snapshots in time, with a repository and update structure that always gives you the latest packages when you run `yum update -y`.

The repository structure is configured to deliver a continuous flow of updates that allow you to roll from one version of Amazon Linux to the next. For example, if you launch an instance from an older version of the Amazon Linux AMI (such as 2013.09 or earlier) and run `yum update -y`, you end up with the latest packages.

You can disable rolling updates for Amazon Linux by enabling the lock-on-launch feature. The lock-on-launch feature locks your newly launched instance to receive updates only from the specified release of the AMI. For example, you can launch a 2013.09 AMI and have it receive only the updates that were released prior to the 2014.03 AMI, until you are ready to migrate to the 2014.03 AMI. To enable lock-on-launch in new instances, launch it with the following user data passed to cloud-init, using either the Amazon EC2 console or the `ec2-run-instances` command with the -f flag.

```
#cloud-config
repo_releasever: 2013.09
```

To lock existing instances to their current AMI release version

1. Edit /etc/yum.conf.
2. Comment out `releasever=latest`.
3. Run `yum clean all` to clear the cache.
Adding Packages

Amazon Linux is designed to be used with online package repositories hosted in each Amazon EC2 region. These repositories provide ongoing updates to packages in the Amazon Linux AMI, as well as access to hundreds of additional common open source server applications. The repositories are available in all regions and are accessed using **yum** update tools, as well as on the Amazon Linux AMI packages site. Hosting repositories in each region enables us to deploy updates quickly and without any data transfer charges. The packages can be installed by issuing **yum** commands, such as the following example:

```
[ec2-user ~]$
```

```
sudo yum install httpd
```

Access to the Extra Packages for Enterprise Linux (EPEL) repository is configured, but it is not enabled by default. EPEL provides third-party packages in addition to those that are in the Amazon Linux repositories. The third-party packages are not supported by AWS.

If you find that Amazon Linux does not contain an application you need, you can simply install the application directly on your Amazon Linux instance. Amazon Linux uses RPMs and **yum** for package management, and that is likely the simplest way to install new applications. You should always check to see if an application is available in our central Amazon Linux repository first, because many applications are available there. These applications can easily be added to your Amazon Linux instance.

To upload your applications onto a running Amazon Linux instance, use **scp** or **sftp** and then configure the application by logging on to your instance. Your applications can also be uploaded during the instance launch by using the PACKAGE_SETUP action from the built-in cloud-init package. For more information, see **cloud-init** (p. 87).

**Important**

If your instance is running in a virtual private cloud (VPC), you must attach an Internet Gateway to the VPC in order to contact the **yum** repository. For more information, see Internet Gateways in the Amazon Virtual Private Cloud User Guide.

Accessing Source Packages for Reference

You can view the source of packages you have installed on your instance for reference purposes by using tools provided in Amazon Linux. Source packages are available for all of the packages included in Amazon Linux and the online package repository. Simply determine the package name for the source package you want to install and use the **get_reference_source** command to view source within your running instance. For example:

```
[ec2-user ~]$
```

```
get_reference_source ~p bash
```

The following is a sample response:

```
Requested package: bash
Found package from local RPM database: bash-4.1.2-15.17.amzn1.x86_64
Corresponding source RPM to found package:
bash-4.1.2-15.17.amzn1.src.rpm
Are these parameters correct? Please type 'yes' to continue: yes
Source RPM downloaded to:
/usr/src/srpm/debug/bash-4.1.2-15.17.amzn1.src.rpm
```

The source RPM is placed in the /usr/src/srpm/debug directory of your instance. From there, it can be unpacked, and, for reference, you can view the source tree using standard RPM tools. After you finish debugging, the package is available for use.
Important
If your instance is running in a virtual private cloud (VPC), you must attach an Internet Gateway to the VPC in order to contact the yum repository. For more information, see Internet Gateways in the Amazon Virtual Private Cloud User Guide.

Developing Applications
A full set of Linux development tools is provided in the yum repository for Amazon Linux. To develop applications on Amazon Linux, select the development tools you need with yum. Alternatively, many applications developed on CentOS and other similar distributions should run on Amazon Linux.

Instance Store Access
The instance store drive ephemeral0 is mounted in /media/ephemeral0 only on Amazon instance store-backed AMIs. This is different than many other images that mount the instance store drive under /mnt.

Product Life Cycle
The Amazon Linux AMI is updated regularly with security and feature enhancements. If you do not need to preserve data or customizations on your Amazon Linux instances, you can simply relaunch new instances with the latest Amazon Linux AMI. If you need to preserve data or customizations for your Amazon Linux instances, you can maintain those instances through the Amazon Linux yum repositories. The yum repositories contain all the updated packages. You can chose to apply these updates to your running instances.

Older versions of the AMI and update packages will continue to be available for use, even as new versions are released. In some cases, if you’re seeking support for an older version of Amazon Linux; through AWS Support, we might ask you to move to newer versions as part of the support process.

Security Updates
Security updates are provided via the Amazon Linux AMI yum repositories as well as via updated Amazon Linux AMIs. Security alerts are published in the Amazon Linux AMI Security Center. For more information on AWS security policies or to report a security problem, go to the AWS Security Center.

Amazon Linux AMIs are configured to download and install security updates at launch time. This is controlled via a cloud-init setting called repo_upgrade. The following snippet of cloud-init configuration shows how you can change the settings in the user data text you pass to your instance initialization:

```
#cloud-config
repo_upgrade: security
```

The possible values for the repo_upgrade setting are as follows:

- **security**
  - Apply outstanding updates that Amazon marks as security updates.

- **bugfix**
  - Apply updates that Amazon marks as bug fixes. Bug fixes are a larger set of updates, which include security updates and fixes for various other minor bugs.

- **all**
  - Apply all applicable available updates, regardless of their classification.
Do not apply any updates to the instance on startup.

The default setting for repo_upgrade is security. That is, if you don't specify a different value in your user data, by default, the Amazon Linux AMI performs the security upgrades at launch for any packages installed at that time. The Amazon Linux AMI also notifies you of any updates to the installed packages by listing the number of available updates upon login using the /etc/motd file. To install these updates, you need to run `sudo yum upgrade` on the instance.

Important
If your instance is running in a virtual private cloud (VPC), you must attach an Internet Gateway to the VPC in order to contact the `yum` repository. For more information, see Internet Gateways in the Amazon Virtual Private Cloud User Guide.

Support
Support for installation and use of the base Amazon Linux AMI is included through subscriptions to AWS Support. For more information, see AWS Support.

We encourage you to post any questions you have about Amazon Linux to the Amazon EC2 forum.

Using Your Own Linux Kernels

To enable user-provided kernels on instances, Amazon has published Amazon Kernel Images (AKIs) that use a system called **PV-GRUB**. PV-GRUB is a paravirtual boot loader that runs a patched version of GNU GRUB 0.97. When you start an instance, PV-GRUB loads the kernel specified by your image's `menu.lst` file.

PV-GRUB understands standard `grub.conf` or `menu.lst` commands, which allows it to work with all currently supported Linux distributions. Older distributions such as Ubuntu 10.04 LTS, Oracle Enterprise Linux or CentOS 5.x require a special "ec2" or "xen" kernel package, while newer distributions include the required drivers in the default kernel package.

Most modern paravirtual AMIs use a PV-GRUB AKI by default (including all of the paravirtual Linux AMIs available in the Amazon EC2 Launch Wizard Quick Start menu), so there are no additional steps that you need to take to use a different kernel on your instance, provided that the kernel you want to use is compatible with your distribution. You can verify that the kernel image for an AMI is a PV-GRUB AKI by executing the following command with the Amazon EC2 command line tools (substituting the kernel image ID you want to check):

```
$ ec2-describe-images -a -F image-id=aki-880531cd
IMAGE  aki-880531cd    amazon/pv-grub-hd0_1.04-x86_64.gz ...
```

The name field of the output should contain `pv-grub`.

Topics
- Limitations of PV-GRUB (p. 92)
- Configuring GRUB (p. 92)
- Amazon PV-GRUB Kernel Image IDs (p. 93)
- Updating PV-GRUB (p. 95)
**Limitations of PV-GRUB**

PV-GRUB has the following limitations:

- You can't use the 64-bit version of PV-GRUB to start a 32-bit kernel or vice versa.
- You can't specify an Amazon ramdisk image (ARI) when using a PV-GRUB AKI.
- AWS has tested and verified that PV-GRUB works with these file system formats: EXT2, EXT3, EXT4, JFS, XFS, and ReiserFS. Other file system formats might not work.
- PV-GRUB can boot kernels compressed using the gzip, bzip2, lzo, and xz compression formats.
- Cluster AMIs don't support or need PV-GRUB, because they use full hardware virtualization (HVM). While paravirtual instances use PV-GRUB to boot, HVM instance volumes are treated like actual disks, and the boot process is similar to the boot process of a bare metal operating system with a partitioned disk and bootloader.
- PV-GRUB versions 1.03 and earlier don't support GPT partitioning; they support MBR partitioning only.
- If you plan to use a logical volume manager (LVM) with Amazon EBS volumes, you need a separate boot partition outside of the LVM. Then you can create logical volumes with the LVM.

**Configuring GRUB**

To boot PV-GRUB, a GRUB `menu.lst` file must exist in the image; the most common location for this file is `/boot/grub/menu.lst`.

The following is an example of a `menu.lst` configuration file for booting an AMI with a PV-GRUB AKI. In this example, there are two kernel entries to choose from: Amazon Linux 2013.09 (the original kernel for this AMI), and Vanilla Linux 3.11.6 (a newer version of the Vanilla Linux kernel from https://www.kernel.org/). The Vanilla entry was copied from the original entry for this AMI, and the `kernel` and `initrd` paths were updated to the new locations. The `default 0` parameter points the bootloader to the first entry it sees (in this case, the Vanilla entry), and the `fallback 1` parameter points the bootloader to the next entry if there is a problem booting the first.

```plain
default 0
fallback 1
timeout 0
hiddenmenu

title Vanilla Linux 3.11.6
root (hd0)
kernal /boot/vmlinuz-3.11.6 root=LABEL=/ console=hvc0
initrd /boot/initrd.img-3.11.6

title Amazon Linux 2013.09 (3.4.62-53.42.amzn1.x86_64)
root (hd0)
kernal /boot/vmlinuz-3.4.62-53.42.amzn1.x86_64 root=LABEL=/ console=hvc0
initrd /boot/initramfs-3.4.62-53.42.amzn1.x86_64.img
```

You don't need to specify a fallback kernel in your `menu.lst` file, but we recommend that you have a fallback when you test a new kernel. PV-GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel allows the instance to boot even if the new kernel isn't found.

PV-GRUB checks the following locations for `menu.lst`, using the first one it finds:

- `(hd0)/boot/grub`
- `(hd0,0)/boot/grub`
Note that PV-GRUB 1.03 and earlier only check one of the first two locations in this list.

Amazon PV-GRUB Kernel Image IDs

PV-GRUB AKIs are available in all Amazon EC2 regions. There are AKIs for both 32-bit and 64-bit architecture types. Most modern AMIs use a PV-GRUB AKI by default.

We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Use the following command to get a list of the PV-GRUB AKIs for the current region:

```
$ ec2-describe-images -o amazon --filter "name=pv-grub-*.gz"
```

Note that PV-GRUB is the only AKI available in the ap-southeast-2 region. You should verify that any AMI you want to copy to this region is using a version of PV-GRUB that is available in this region.

The following are the current AKI IDs for each region. There is no longer any difference between the hd0 and hd00 AKIs, though we continue to provide both naming schemes for backward compatibility. You should register new AMIs using an hd0 AKI.

Updating PV-GRUB

We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Also, older versions of PV-GRUB are not available in all regions, so if you copy an AMI that uses an older version to a region that does not support that version, you will be unable to boot instances launched from that AMI until you update the kernel image. Use the following procedures to check your instance's version of PV-GRUB and update it if necessary.

To check your PV-GRUB version

1. Find the kernel ID for your instance.

   ```bash
   $ ec2-describe-instance-attribute instance_id --kernel --region region
   kernel instance_id aki-fc8f1lcc
   ```

   The kernel ID for this instance is aki-fc8f1lcc.

2. View the version information of that kernel ID.

   ```bash
   $ ec2-describe-images aki-fc8f1lcc --region region
   IMAGE aki-fc8f1lcc amazon/pv-grub-hd0_1.04-x86_64.gz ...
   ```

   This kernel image is PV-GRUB 1.04. If your PV-GRUB version is not the newest version (as shown in Amazon PV-GRUB Kernel Image IDs (p. 93)), you should update it using the following procedure.

To update your PV-GRUB version

If your instance is using an older version of PV-GRUB, you should update it to the latest version.

1. Identify the latest PV-GRUB AKI for your region and processor architecture from Amazon PV-GRUB Kernel Image IDs (p. 93).
2. Stop your instance. Your instance must be stopped to modify the kernel image used.

   
   $ ec2-stop-instances instance_id --region region
   
   INSTANCE instance_id stopped stopped

3. Modify the kernel image used for your instance.

   
   $ ec2-modify-instance-attribute --kernel kernel_id --region region instance_id

4. Restart your instance.

   
   $ ec2-start-instances --region region instance_id

If you're new to Amazon EC2, see the following topics to get started:

- What Is Amazon EC2? (p. 1)
- Setting Up with Amazon EC2 (p. 19)
- Getting Started with Amazon EC2 Linux Instances (p. 24)
- Getting Started with Amazon EC2 Windows Instances
- Instance Lifecycle (p. 297)

Before you launch a production environment, you need to answer the following questions.

**Q. What purchasing option best meets my needs?**
Amazon EC2 supports On-Demand Instances (the default), Spot Instances (p. 121), and ReservedInstances (p. 198). For more information, see Amazon EC2 Pricing.

**Q. What instance type best meets my needs?**
Amazon EC2 provides different instance types to enable you to choose the CPU, memory, storage, and networking capacity that you need to run your applications. For more information, see InstanceTypes (p. 97).

**Q. Which type of root volume meets my needs?**
Each instance is backed by Amazon EBS or backed by instance store. Select an AMI based on which type of root volume you need. For more information, see Storage for the Root Device (p. 50).

**Q. Would I benefit from using a virtual private cloud?**
If you can launch instances in either EC2-Classic or EC2-VPC, you'll need to decide which platform meets your needs. For more information, see Supported Platforms (p. 487) and Amazon EC2 and Amazon Virtual Private Cloud (VPC) (p. 485).

## Instance Types

When you launch an instance, the instance type that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance.

Amazon EC2 provides each instance with a consistent and predictable amount of CPU capacity, regardless of its underlying hardware.
Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is under-utilized, an instance can consume a higher share of that resource while it's available.

Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

The maximum transmission unit (MTU) for an instance depends on its instance type. The following instance types provide 9001 MTU (jumbo frames): CC2, C3, R3, CG1, CR1, G2, HS1, HI1, I2, and M3. The other instance types provide 1500 MTU (Ethernet v2 frames).

To obtain additional, dedicated capacity for Amazon EBS I/O, you can launch some instance types as Amazon EBS-optimized instances. For more information, see Amazon EBS-Optimized Instances (p. 114).

To optimize your instances for high performance computing (HPC) applications, you can launch some instance types in a placement group. For more information, see Placement Groups (p. 115).

When you launch your instance, it uses one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The virtualization type is determined by the AMI used to launch the instance; some instance types support both PV and HVM while others support only one or the other. HVM virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses PV network and storage drivers for improved performance.

## Hardware Specifications

For more information about the hardware specifications for each Amazon EC2 instance type, see Instance Type Details.
To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance hour, it's convenient and inexpensive to test multiple instance types before making a decision. If your needs change, you can resize your instance later on. For more information, see Resizing Your Instance (p. 118).

**Micro Instances**

Micro instances (t1.micro) provide a small amount of consistent CPU resources and allow you to increase CPU capacity in short bursts when additional cycles are available. They are well suited for lower throughput applications and websites that require additional compute cycles periodically.

The t1.micro instance is available as an Amazon EBS-backed instance only.

This documentation describes how t1.micro instances work so that you can understand how to apply them. It's not our intent to specify exact behavior, but to give you visibility into the instance's behavior so you can understand its performance (to a greater degree than you typically get with, for example, a multi-tenant shared web hosting system).

**Hardware Specifications**

For more information about the hardware specifications for each Amazon EC2 instance type, see Instance Type Details.

**Optimal Application of Micro Instances**

A t1.micro instance provides spiky CPU resources for workloads that have a CPU usage profile similar to what is shown in the following figure.
The instance is designed to operate with its CPU usage at essentially only two levels: the normal low background level, and then at brief spiked levels much higher than the background level. We allow the instance to operate at up to 2 EC2 compute units (ECUs) (one ECU provides the equivalent CPU capacity of a 1.0-1.2 GHz 2007 Opteron or 2007 Xeon processor). The ratio between the maximum level and the background level is designed to be large. We designed \texttt{t1.micro} instances to support tens of requests per minute on your application. However, actual performance can vary significantly depending on the amount of CPU resources required for each request on your application.

Your application might have a different CPU usage profile than that described in the preceding section. The next figure shows the profile for an application that isn't appropriate for a \texttt{t1.micro} instance. The application requires continuous data-crunching CPU resources for each request, resulting in plateaus of CPU usage that the \texttt{t1.micro} instance isn't designed to handle.

The next figure shows another profile that isn't appropriate for a \texttt{t1.micro} instance. Here the spikes in CPU use are brief, but they occur too frequently to be serviced by a \texttt{micro} instance.
The next figure shows another profile that isn't appropriate for a \texttt{t1.micro} instance. Here the spikes aren't too frequent, but the background level between spikes is too high to be serviced by a \texttt{t1.micro} instance.

In each of the preceding cases of workloads not appropriate for a \texttt{t1.micro} instance, we recommend that you consider using a different instance type. For more information about instance types, see \textit{Instance Types} (p. 97).

**Available CPU Resources During Spikes**

When your instance \textit{bursts} to accommodate a spike in demand for compute resources, it uses unused resources on the host. The amount available depends on how much contention there is when the spike occurs. The instance is never left with zero CPU resources, whether other instances on the host are spiking or not.
When the Instance Uses Its Allotted Resources

We expect your application to consume only a certain amount of CPU resources in a period of time. If the application consumes more than your instance's allotted CPU resources, we temporarily limit the instance so it operates at a low CPU level. If your instance continues to use all of its allotted resources, its performance will degrade. We will increase the time that we limit its CPU level, thus increasing the time before the instance is allowed to burst again.

If you enable CloudWatch monitoring for your t1.micro instance, you can use the "Avg CPU Utilization" graph in the AWS Management Console to determine whether your instance is regularly using all its allotted CPU resources. We recommend that you look at the maximum value reached during each given period. If the maximum value is 100%, we recommend that you use Auto Scaling to scale out (with additional t1.micro instances and a load balancer), or move to a larger instance type. For more information, see the Auto Scaling Developer Guide.

The following figures show the three suboptimal profiles from the preceding section and what it might look like when the instance consumes its allotted resources and we have to limit its CPU level. If the instance consumes its allotted resources, we restrict it to the low background level.

The next figure shows the situation with the long plateaus of data-crunching CPU usage. The CPU hits the maximum allowed level and stays there until the instance's allotted resources are consumed for the period. At that point, we limit the instance to operate at the low background level, and it operates there until we allow it to burst above that level again. The instance again stays there until the allotted resources are consumed and we limit it again (not seen on the graph).

The next figure shows the situation where the requests are too frequent. The instance uses its allotted resources after only a few requests and so we limit it. After we lift the restriction, the instance maxes out its CPU usage trying to keep up with the requests, and we limit it again.
The next figure shows the situation where the background level is too high. Notice that the instance doesn't have to be operating at the maximum CPU level for us to limit it. We limit the instance when it's operating above the normal background level and has consumed its allotted resources for the given period. In this case (as in the preceding one), the instance can't keep up with the work, and we limit it again.

**Comparison with the m1.small Instance Type**

The t1.micro instance provides different levels of CPU resources at different times (up to 2 ECUs). By comparison, the m1.small instance type provides 1 ECU at all times. The following figure illustrates the difference.
The following figures compare the CPU usage of a t1.micro instance with an m1.small instance for the various scenarios we've discussed in the preceding sections.

The first figure that follows shows an optimal scenario for a t1.micro instance (the left graph) and how it might look for an m1.small instance (the right graph). In this case, we don’t need to limit the t1.micro instance. The processing time on the m1.small instance would be longer for each spike in CPU demand compared to the t1.micro instance.

The next figure shows the scenario with the data-crunching requests that used up the allotted resources on the t1.micro instance, and how they might look with the m1.small instance.
The next figure shows the frequent requests that used up the allotted resources on the \texttt{t1.micro} instance, and how they might look on the \texttt{m1.small} instance.

The next figure shows the situation where the background level used up the allotted resources on the \texttt{t1.micro} instance, and how it might look on the \texttt{m1.small} instance.

**AMI Optimization for Micro Instances**

We recommend that you follow these best practices when optimizing an AMI for the \texttt{t1.micro} instance type:

- Design the AMI to run on 600 MB of RAM
- Limit the number of recurring processes that use CPU time (for example, cron jobs, daemons)

In Linux, you can optimize performance using swap space and virtual memory (for example, by setting up swap space in a separate partition from the root file system).
In Windows, when you perform significant AMI or instance configuration changes (for example, enable server roles or install large applications), you might see limited instance performance, because these changes can be memory intensive and require long-running CPU resources. We recommend that you first use a larger instance type when performing these changes to the AMI, and then run the AMI on a t1.micro instance for normal operations.

I2 Instances

I2 instances are optimized to deliver tens of thousands of low-latency, random I/O operations per second (IOPS) to applications. They are well suited for the following scenarios:

- NoSQL databases (for example, Cassandra and MongoDB)
- Clustered databases
- Online transaction processing (OLTP) systems

You can cluster I2 instances in a placement group. Cluster placement groups provide low latency and high-bandwidth connectivity between the instances within a single Availability Zone. For more information, see Placement Groups (p. 115).

You can enable enhanced networking capabilities for I2 instances. For more information, see Enabling Enhanced Networking on Linux Instances in a VPC (p. 516) or Enabling Enhanced Networking on Windows Instances in a VPC.

Hardware Specifications

For more information about the hardware specifications for each Amazon EC2 instance type, see Instance Type Details.

I2 Instance Limitations

You must launch an I2 instance using an HVM AMI. We support the following Linux distributions: Amazon Linux, Ubuntu, Red Hat Enterprise Linux, and SUSE Enterprise Linux. We support the following versions of Windows: Microsoft Windows Server 2012 and Microsoft Windows Server 2008 R2. If you’d like to use an HVM AMI for a different operating system, let us know by posting to the Amazon EC2 forum.

We limit the number of I2 instances that you can run. If you need more I2 instances than the default limits described in the following table, you can request more I2 instances using the Amazon EC2 Instance Request Form.

<table>
<thead>
<tr>
<th>Instance Size</th>
<th>Default Instance Limit</th>
</tr>

<td>8</td>
</tr>
<tr>
<td>i2.4xlarge</td>
<td>4</td>
</tr>
<tr>
<td>i2.8xlarge</td>
<td>2</td>
</tr>
</tbody>
</table>
SSD Storage

The primary data storage for I2 instances is SSD-based instance storage. Like all instance storage, these volumes persist only for the life of the instance. When you terminate an instance, the applications and data in its instance store is erased. When you use an Amazon EBS-backed AMI, you can start and stop your instance. However, when you stop an instance, the data stored in the Amazon EBS volume persists, but data in the instance store volumes doesn't persist. We recommend that you regularly back up or replicate the data you've stored in instance storage.

For more information about instance store volumes, see Amazon EC2 Instance Store (p. 582).

SSD I/O Performance

To ensure the best IOPS performance from your I2 instance, we recommend that you use the most recent version of the Amazon Linux AMI, or another Linux AMI with kernel version 3.8 or later. If you use a Linux AMI with kernel version 3.8 or later and utilize all the SSD-based instance store volumes available to the instance, you can get at least the minimum random IOPS (4,096 byte block size) listed in the following table. Otherwise, you'll get lower IOPS performance than what is shown in the table.

<table>
<thead>
<tr>
<th>Instance Size</th>

</tr>
</tbody>
</table>

As you fill the SSD-based instance storage for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called over-provisioning. The SSD-based instance store volumes provided to an I2 instance don't have any space reserved for over-provisioning. To reduce write amplification, you should leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance.

You can also use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information about using TRIM commands, see the documentation for the operating system for your instance.

HI1 Instances

HI1 instances (hi1.4xlarge) can deliver tens of thousands of low-latency, random I/O operations per second (IOPS) to applications. They are well suited for the following scenarios:

- NoSQL databases (for example, Cassandra and MongoDB)
• Clustered databases
• Online transaction processing (OLTP) systems

You can cluster HI1 instances in a placement group. For more information, see Placement Groups (p. 115).

By default, you can run up to two hi1.4xlarge instances. If you need more than two hi1.4xlarge instances, you can request more using the Amazon EC2 Instance Request Form.

Topics
• Hardware Specifications (p. 108)
• Disk I/O Performance (p. 108)
• SSD Storage (p. 108)

Hardware Specifications

The hi1.4xlarge instance type is based on solid-state drive (SSD) technology.

For more information about the hardware specifications for each Amazon EC2 instance type, see Instance Type Details.

Disk I/O Performance

Using Linux paravirtual (PV) AMIs, HI1 instances can deliver more than 120,000 4 KB random read IOPS and between 10,000 and 85,000 4 KB random write IOPS (depending on active logical block addressing span) to applications across two SSD data volumes. For hardware virtual machines (HVM) and Windows AMIs, performance is approximately 90,000 4 KB random read IOPS and between 9,000 and 75,000 4 KB random write IOPS.

The maximum sequential throughput on all AMI types (Linux PV, Linux HVM, and Windows) per second is approximately 2 GB read and 1.1 GB write.

SSD Storage

This section contains important information you need to know about SSD storage. With SSD storage:

• The primary data source is an instance store with SSD storage.
• Read performance is consistent and write performance can vary.
• Write amplification can occur.
• The TRIM command is not currently supported.

Instance Store with SSD Storage

The hi1.4xlarge instances use an Amazon EBS-backed root device. However, their primary data storage is provided by the SSD volumes in the instance store. Like other instance store volumes, these instance store volumes persist only for the life of the instance. Because the root device of the hi1.4xlarge instance is Amazon EBS-backed, you can still start and stop your instance. When you stop an instance, your application persists, but your production data in the instance store does not persist. For more information about instance store volumes, see Amazon EC2 Instance Store (p. 582).

Variable Write Performance

Write performance depends on how your applications utilize logical block addressing (LBA) space. If your applications use the total LBA space, write performance can degrade by about 90 percent. Benchmark
your applications and monitor the queue depth (the number of pending I/O requests for a volume) and I/O size.

**Write Amplification**

Write amplification refers to an undesirable condition associated with flash memory and SSDs, where the actual amount of physical information written is a multiple of the logical amount intended to be written. Because flash memory must be erased before it can be rewritten, the process to perform these operations results in moving (or rewriting) user data and metadata more than once. This multiplying effect increases the number of writes required over the life of the SSD, which shortens the time that it can reliably operate. The hi1.4xlarge instances are designed with a provisioning model intended to minimize write amplification.

Random writes have a much more severe impact on write amplification than serial writes. If you are concerned about write amplification, allocate less than the full tebibyte of storage for your application (also known as over provisioning).

**The TRIM Command**

The TRIM command enables the operating system to notify an SSD that blocks of previously saved data are considered no longer in use. TRIM limits the impact of write amplification.

TRIM support is not available for HI1 instances. For TRIM support, use I2 instances. For more information, see [I2 Instances](p. 106).

**HS1 Instances**

HS1 instances (hs1.8xlarge) provide very high storage density and high sequential read and write performance per instance. They are well suited for the following scenarios:

- Data warehousing
- Hadoop/MapReduce
- Parallel file systems

You can cluster HS1 instances in a placement group. For more information, see [Placement Groups](p. 115).

By default, you can run up to two HS1 instances. If you need more than two HS1 instances, you can request more using the [Amazon EC2 Instance Request Form](#).

**Topics**

- Hardware Specifications (p. 109)
- Disk I/O Performance (p. 110)
- Storage Information (p. 110)

**Hardware Specifications**

HS1 instances support both Amazon Elastic Block Store (Amazon EBS)-backed and instance store-backed Amazon Machine Images (AMIs). HS1 instances support both paravirtual (PV) and hardware virtual machine (HVM) AMIs. HS1 instances are capable of delivering 2.4 GB per second of sequential read and 2.6 GB per second of sequential write performance when using a block size of 2 MiB.

For customers using Microsoft Windows Server, HS1 instances are only supported with the Microsoft Windows Server AMIs for Cluster Instance Type. HS1 instances do not currently support Amazon EBS...
optimization, but provide high bandwidth networking and can also be used with Amazon EBS provisioned I/O operations per second (IOPS) volumes for improved consistency and performance.

For more information about the hardware specifications for each Amazon EC2 instance type, see Instance Type Details.

**Disk I/O Performance**

HS1 instances are capable of delivering 2.6 GB per second of sequential read and write performance when using a block size of 2 MiB.

**Storage Information**

This section contains important information you need to know about the storage used with HS1 instances.

**Instance Store with HS1 Instances**

HS1 instances support both instance store and Amazon EBS root device volumes. However, even when using an Amazon EBS-backed instance, primary data storage is provided by the hard disk drives in the instance store. Like other instance store volumes, these instance store volumes persist only for the life of the instance. Therefore, when you stop an instance (when using an Amazon EBS-backed root volume), your application persists, but your production data in the instance store does not persist. For more information about instance store volumes, see Amazon EC2 Instance Store (p. 582).

**Disk Initialization**

If you plan to run an HS1 instance in a steady state for long periods of time, we recommend that you zero the hard disks first for improved performance. This process can take as long as six hours to complete.

**Setting the Memory Limit**

Many Linux-based AMIs come with `CONFIG_XEN_MAX_DOMAIN_MEMORY` set to 70. We recommend that you set this as appropriate for 117 GiB of memory.

**Setting the User Limit (ulimit)**

Many Linux-based AMIs come with a default ulimit of 1024. We recommend that you increase the ulimit to 2048.

**R3 Instances**

R3 instances are optimized to deliver high memory performance and high sustainable bandwidth. They are well suited for the following scenarios:

- Relational databases and NoSQL databases (for example, MongoDB)
- In-memory analytics
- Memcache/Redis applications (for example, Elasticache)

You can cluster R3 instances in a placement group. Cluster placement groups provide low latency and high-bandwidth connectivity between the instances within a single Availability Zone. For more information, see Placement Groups (p. 115).

You can enable enhanced networking capabilities for R3 instances. For more information, see Enabling Enhanced Networking on Linux Instances in a VPC (p. 516) or Enabling Enhanced Networking on Windows Instances in a VPC.

Hardware Specifications

Operating System Support

We support the following Linux operating systems: Amazon Linux, Ubuntu, Red Hat Enterprise Linux, and SUSE Enterprise Linux. In addition, you can launch R3 instances using Microsoft Windows Server 2012 and Microsoft Server 2008 R2 AMIs. If you’d like to use an HVM AMI for a different operating system, let us know by posting to the Amazon EC2 forum.

HVM AMI Support

R3 instances have high-memory (up to 244 GiB of RAM), and require 64-bit operating systems to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. For these reasons, R3 instances support 64-bit HVM AMIs only. In addition, HVM AMIs are required to leverage the benefits of enhanced networking.

Default R3 Instance Limits

We limit the number of R3 instances that you can run simultaneously. If you need more R3 instances than the default limits described in the following table, you can request more by using the Amazon EC2 Instance Request Form.

<table>
<thead>
<tr>
<th>Instance Type</th>
<th>Default Instance Limit</th>
</tr>
</thead>

<td>20</td>
</tr>
<tr>
<td>r3.4xlarge</td>
<td>10</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>5</td>
</tr>
</tbody>
</table>

SSD Storage

The primary data storage for R3 instances is SSD-based instance storage. Like all instance storage, these volumes persist only for the life of the instance. When you terminate an instance, the applications and data in its instance store are erased. When you use an Amazon EBS-backed AMI, you have the option to stop your instance and restart it later; however, when you stop an instance, the data stored in
the Amazon EBS volumes persist, but data in the instance store volumes is lost. We recommend that you regularly back up or replicate the data you've stored in instance storage.

For more information about instance store volumes, see Amazon EC2 Instance Store (p. 582).

SSD I/O Performance

The largest R3 instances (r3.8xlarge) are capable of providing up to 150,000 4 kilobyte (KB) random read IOPS and up to 130,000 4 KB random first write IOPS. To ensure the best IOPS performance from your R3 instance, we recommend that you use the most recent version of the Amazon Linux AMI, or another Linux AMI with a kernel version of 3.8 or later. If you do not use a Linux AMI with a kernel version of 3.8 or later, you will not achieve the maximum IOPS performance available for this instance type.

TRIM Support

You can also use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information about using TRIM commands, see the operating system-specific documentation for your instance.

GPU Instances

If you require high parallel processing capability, you'll benefit from using GPU instances, which provide access to NVIDIA GPUs with up to 1,536 CUDA cores and 4 GB of video memory. You can use GPU instances to accelerate many scientific, engineering, and rendering applications by leveraging the Compute Unified Device Architecture (CUDA) or OpenCL parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

GPU instances run as HVM-based instances. Hardware virtual machine (HVM) virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses paravirtual (PV) network and storage drivers for improved performance. This enables Amazon EC2 to provide dedicated access to one or more discrete GPUs in each GPU instance.

You can cluster GPU instances into a cluster placement group. Cluster placement groups provide low latency and high-bandwidth connectivity between the instances within a single Availability Zone. For more information, see Placement Groups (p. 115).

GPU Instance Limitations

GPU instances currently have the following limitations:
• They aren't available in every region.
• They must be launched from HVM AMIs.
• They can't access the GPU unless the NVIDIA drivers are installed.
• They aren't available for use with Amazon DevPay.
• We limit the number of instances that you can run. For more information, see How many instances can I run in Amazon EC2? in the Amazon EC2 FAQ. To request an increase in these limits, use the following form: Request to Increase Amazon EC2 Instance Limit.

AMIs for GPU Instances

To help you get started, NVIDIA provides AMIs for GPU instances for Amazon Linux and Windows. These reference AMIs include the NVIDIA driver, which enables full functionality and performance of the NVIDIA GPUs. For a list of AMIs with the NVIDIA driver, see AWS Marketplace (NVIDIA GRID).

You can launch a CG1 instance using any HVM AMI.

You can launch a G2 instance using Windows Server 2012 and Windows Server 2008 R2 AMIs. In addition, you can launch Linux HVM AMIs with the following operating systems: Amazon Linux, SUSE Enterprise Linux, and Ubuntu. If you encounter the following error when launching a G2 instance from an AMI for a different operating system, contact Customer Service or reach out through the Amazon EC2 forum.

Client.UnsupportedOperation: Instances of type 'g2.2xlarge' may not be launched from AMI <ami-id>.

After you launch a G2 instance, you can create your own AMI from the instance. However, if you create a snapshot of the root volume of the instance, register it as an AMI, and then launch a G2 instance, you'll get the Client.UnsupportedOperation error. To launch a G2 instance from your own AMI, you must create the AMI from a G2 instance using the console (select the instance, click Actions, and then click Create Image), create-image (AWS CLI), or ec2-create-image (Amazon EC2 CLI).

Installing the NVIDIA Driver on Linux

A GPU instance must have the appropriate NVIDIA driver. The NVIDIA driver you install must be compiled against the kernel that you intend to run on your instance.

Amazon provides updated and compatible builds of the NVIDIA kernel drivers for each official kernel upgrade. If you decide to use a different NVIDIA driver version than the one Amazon provides, or decide to use a kernel that's not an official Amazon build, you must uninstall the Amazon-provided NVIDIA packages from your system to avoid conflicts with the versions of the drivers you are trying to install.

Use this command to uninstall Amazon-provided NVIDIA packages:

```bash
$ sudo yum erase nvidia cudatoolkit
```

The Amazon-provided CUDA toolkit package has dependencies on the NVIDIA drivers. Uninstalling the NVIDIA packages erases the CUDA toolkit. You must reinstall the CUDA toolkit after installing the NVIDIA driver.

You can download NVIDIA drivers from http://www.nvidia.com/Download/Find.aspx. Select a driver for the NVIDIA GRID K520 (G2 instances) or Tesla M-Class M2050 (CG1 instances) for Linux 64-bit systems. For more information about installing and configuring the driver, open the ADDITIONAL INFORMATION tab on the download page for the driver on the NVIDIA website and click the README link.
Manually Install the NVIDIA Driver

To install the driver for an Amazon Linux AMI

1. Make sure the `kernel-devel` package is installed and matches the version of the kernel you are currently running.

   ```bash
   $ yum install kernel-devel-`uname -r`
   ```

2. Run the self-install script to install the NVIDIA driver. For example:

   ```bash
   $ /root/NVIDIA-Linux-x86_64_319.60.run
   ```

3. Reboot the instance. For more information, see Reboot Your Instance (p. 322).

4. Confirm that the driver is functional. The response for the following command lists the installed NVIDIA driver version and details about the GPUs.

   ```bash
   $ /usr/bin/nvidia-smi -q -a
   ```

Installing the NVIDIA Driver on Windows

To install the NVIDIA driver on your Windows instance, log on to your instance as Administrator using Remote Desktop. You can download NVIDIA drivers from [http://www.nvidia.com/Download/Find.aspx](http://www.nvidia.com/Download/Find.aspx). Select a driver for the NVIDIA GRID K520 (G2 instances) or Tesla M-Class M2050 (CG1 instances) for your version of Windows Server. Open the folder where you downloaded the driver and double-click the installation file to launch it. Follow the instructions to install the driver and reboot your instance as required. To verify that the GPU is working properly, check device manager.

When using Remote Desktop, GPUs that use the WDDM driver model are replaced with a non-accelerated Remote Desktop display driver. In order to access your GPU hardware, you must use a different remote access tool, such as VNC. You can also use one of the GPU AMIs from the AWS Marketplace because they provide remote access tools that support 3-D acceleration.

Amazon EBS-Optimized Instances

An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your Amazon EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

When you use an Amazon EBS-optimized instance, you pay an additional low, hourly fee for the dedicated capacity.

Amazon EBS optimization enables instances to fully utilize the IOPS provisioned on an Amazon EBS volume. Amazon EBS-optimized instances deliver dedicated throughput to Amazon EBS, with options between 500 Mbps and 2,000 Mbps, depending on the instance type you use. When attached to an Amazon EBS-optimized instance, Provisioned IOPS volumes are designed to deliver within 10 percent of their provisioned performance 99.9 percent of the time in a given year. For more information, see Provisioned IOPS Volumes (p. 526).

The table below describes the instance types that can be launched as Amazon EBS-optimized instances, the dedicated Amazon EBS throughput they provide, and the maximum number of input/output operations per second (IOPS) that you can drive over the Amazon EBS connection.

To launch an Amazon EBS-optimized instance, select the **Launch as EBS-optimized instance** option in the launch wizard. If the instance type that you've selected can't be launched as an Amazon EBS-optimized instance, this option is not available.

To launch an Amazon EBS-optimized instance using the AWS CLI, use the `run-instances` command with the `--ebs-optimized` option.

To launch an Amazon EBS-optimized instance using Amazon EC2 CLI, use the `ec2-run-instances` command with the `--ebs-optimized` option.

### Placement Groups

A placement group is a logical grouping of instances within a single Availability Zone. Using placement groups enables applications to participate in a low-latency, 10 Gbps network. Placement groups are recommended for applications that benefit from low network latency, high network throughput, or both.

To provide the lowest latency, and the highest packet-per-second network performance for your placement group, choose an instance type that supports enhanced networking. For more information, see Enhanced Networking (p. 516).

First, you create a placement group and then you launch multiple instances into the placement group. We recommend that you launch the number of instances that you need in the placement group in a single launch request. If you try to add more instances to the placement group later, you increase your chances of getting an insufficient capacity error.
If you stop an instance in a placement group and then start it again, it still runs in the placement group. However, the start fails if there isn’t enough capacity for the instance.

If you receive a capacity error when launching an instance in a placement group, stop and restart the instances in the placement group, and then try the launch again.

Placement Group Limitations

Placement groups have the following limitations:

- A placement group can’t span multiple Availability Zones.
- The name you specify for a placement group a name must be unique within your AWS account.
- The following are the only instance types that you can use when you launch an instance into a placement group:
  - Compute optimized: c3.large | c3.xlarge | c3.2xlarge | c3.4xlarge | c3.8xlarge | cc2.8xlarge
  - GPU: cg1.4xlarge | g2.2xlarge
  - Memory optimized: cr1.8xlarge | r3.large | r3.xlarge | r3.2xlarge | r3.4xlarge | r3.8xlarge
  - Storage optimized: hi1.4xlarge | hs1.8xlarge | i2.xlarge | i2.2xlarge | i2.4xlarge | i2.8xlarge
- You can’t merge placement groups. Instead, you must terminate the instances in one placement group, and then relaunch those instances into the other placement group.
- A placement group can span peered VPCs; however, you will not get full-bisection bandwidth between instances in peered VPCs. For more information about VPC peering connections, see VPC Peering in the Amazon Virtual Private Cloud User Guide.

Launching Instances into a Placement Group

We suggest that you create an AMI specifically for the instances that you’ll launch into a placement group.

To launch an instance into a placement group using the console
1. Open the Amazon EC2 console.
2. Create an AMI for your instances.
   a. From the Amazon EC2 dashboard, click Launch Instance. After you complete the wizard, click Launch.
   b. Connect to your instance. (For more information, see Connect to Your Instance (p. 308).)
   c. Install software and applications on the instance, copy data, or attach additional Amazon EBS volumes.
   d. In the navigation pane, click Instances, select your instance, click Actions, and then click Create Image. Provide the information requested by the Create Image dialog box, and then click Create Image.
   e. (Optional) You can terminate this instance if you have no further use for it.
3. Create a placement group.
   a. In the navigation pane, click Placement Groups.
   b. Click Create Placement Group.
   c. In the Create Placement Group dialog box, provide a name for the placement group that is unique in the AWS account you’re using, and then click Create.

   When the status of the placement group is available, you can launch instances into the placement group.

4. Launch your instances into the placement group.
   a. In the navigation pane, click Instances.
   b. Click Launch Instance. Complete the wizard as directed, taking care to select the following:
      • The AMI that you created
      • The number of instances that you’ll need
      • The placement group that you created

To create a placement group using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

• create-placement-group (AWS CLI)
• ec2-create-placement-group (Amazon EC2 CLI)
• New-EC2PlacementGroup (AWS Tools for Windows PowerShell)

If you prefer, you can use the ec2-create-image command to create your AMI, the ec2-create-placement-group command to create your placement group, and use the ec2-run-instances command to launch an instance into the placement group.

Deleting a Placement Group

You can delete a placement group if you need to replace it or no longer need a placement group. Before you can delete your placement group, you must terminate all instances that you launched into the placement group.

To delete a placement group using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click Instances.
3. Select and terminate all instances in the placement group. (You can verify that the instance is in a placement group before you terminate it by checking the value of Placement Group in the details pane.)
4. In the navigation pane, click Placement Groups.
5. Select the placement group, and then click Delete Placement Group.
6. When prompted for confirmation, click Yes, Delete.
To delete a placement group using the command line

You can use one of the following sets of commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `terminate-instances` and `delete-placement-group` (AWS CLI)
- `ec2-terminate-instances` and `ec2-delete-placement-group` (Amazon EC2 CLI)
- `Stop-EC2Instance` and `Remove-EC2PlacementGroup` (AWS Tools for Windows PowerShell)

**Resizing Your Instance**

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can change the size of your instance. For example, if your `t1.micro` instance is too small for its workload, you can change it to an `m1.small` instance.

The process for resizing an instance varies depending on the type of its root device volume, as follows:

- If the root device for your instance is an Amazon EBS volume, you can easily resize your instance by changing its instance type.
- If the root device for your instance is an instance store volume, you must migrate to a new instance.

To determine the root device type of your instance, open the Amazon EC2 console, click **Instances**, select the instance, and check the value of **Root device type** in the details pane. The value is either `ebs` or `instance store`.

For more information about root device volumes, see **Storage for the Root Device** (p. 50).

**Topics**

- Resizing an Amazon EBS-backed Instance (p. 118)
- Resizing an Instance Store-backed Instance (p. 119)

**Resizing an Amazon EBS-backed Instance**

You must stop your Amazon EBS-backed instance before you can change its instance type. When you stop and start an instance, we move it to new hardware. If the instance is running in EC2-Classic, we give it new public and private IP addresses, and disassociate any Elastic IP address that's associated with the instance. Therefore, to ensure that your users can continue to use the applications that you're hosting on your instance uninterrupted, you must re-associate any Elastic IP address after you restart your instance. For more information, see **Stop and Start Your Instance** (p. 319).

Use the following procedure to resize an Amazon EBS-backed instance using the AWS Management Console.

**To resize an Amazon EBS-backed instance**

1. Open the Amazon EC2 console.
2. In the navigation pane, click **Instances**, and select the instance.
3. [EC2-Classic] If the instance has an associated Elastic IP address, write down the Elastic IP address and the instance ID shown in the details pane.
4. Click **Actions**, and then click **Stop**.
5. In the confirmation dialog box, click **Yes, Stop**. It can take a few minutes for the instance to stop.
[EC2-Classic] When the instance state becomes stopped, the Elastic IP, Public DNS, Private DNS, and Private IPs fields in the details pane are blank to indicate that the old values are no longer associated with the instance.

6. With the instance still selected, click Actions, and then click Change Instance Type. Note that this action is disabled if the instance state is not stopped.

7. In the Change Instance Type dialog box, in the Instance Type list, select the type of instance that you need, and then click Apply.

8. To restart the stopped instance, select the instance, click Actions, and then click Start.

9. In the confirmation dialog box, click Yes, Start. It can take a few minutes for the instance to enter the running state.

[EC2-Classic] When the instance state is running, the Public DNS, Private DNS, and Private IPs fields in the details pane contain the new values that we assigned to the instance.

10. [EC2-Classic] If your instance had an associated Elastic IP address, you must reassociate it as follows:
   a. In the navigation pane, click Elastic IPs.
   b. Select the Elastic IP address that you wrote down before you stopped the instance.
   c. Click Associate Address.
   d. Select the instance ID that you wrote down before you stopped the instance, and then click Associate.

**Resizing an Instance Store-backed Instance**

You can create an image from your current instance, launch a new instance from this image with the instance type you need, and then terminate the original instance that you no longer need. To ensure that your users can continue to use the applications that you're hosting on your instance uninterrupted, you must take any Elastic IP address that you've associated with your current instance and associate it with the new instance.

**To resize an instance store-backed instance**

1. (Optional) If the instance you are resizing has an associated Elastic IP address, record the Elastic IP address now so that you can associate it with the resized instance later.

2. Create an AMI from your instance store-backed instance by satisfying the prerequisites and following the procedures in Creating an Instance Store-Backed Linux AMI (p. 72). When you are finished creating a new AMI from your instance, return to this procedure.

3. Open the Amazon EC2 console and in the navigation pane, select AMIs. From the filter lists, select Owned by me, and select the image you created in the previous step. Notice that AMI Name is the name that you specified when you registered the image and Source is your Amazon S3 bucket.

   **Note**
   If you do not see the AMI that you created in the previous step, make sure that the console displays the region that you created your AMI in.

4. Click Launch. When you specify options in the launch wizard, be sure to specify the new instance type that you need. It can take a few minutes for the instance to enter the running state.

5. (Optional) If the instance that you started with had an associated Elastic IP address, you must associate it with the new instance as follows:
   a. In the navigation pane, click Elastic IPs.
   b. Select the Elastic IP address that you recorded at the beginning of this procedure.
   c. Click Associate Address.
d. Select the instance ID of the new instance, and then click **Associate**.

6. (Optional) You can terminate the instance that you started with, if it's no longer needed. Select the instance and check its instance ID against the instance ID that you wrote down at the beginning of this procedure to verify that you are terminating the correct instance. Click **Actions**, and then click **Terminate**.
Spot Instances

If you have flexibility on when your application will run, you can bid on unused Amazon EC2 compute capacity, called Spot Instances, and lower your costs significantly. Set by Amazon EC2, the Spot Price for these instances fluctuates periodically depending on the supply of and demand for Spot Instance capacity.

To use Spot Instances, you place a Spot Instance request (your bid) specifying the maximum price you are willing to pay per hour per instance. If the maximum price of your bid is greater than the current Spot Price, your request is fulfilled and your instances run until you terminate them or the Spot Price increases above your maximum price. Your instance can also be terminated when your bid price equals the market price, even when there is no increase in the market price. This can happen when demand for capacity rises, or when supply fluctuates.

**Note**
You can run Amazon EC2 Spot Instances on the following platforms: Amazon Linux/UNIX, SUSE Linux Enterprise Server, and Windows (without SQL Server). Spot Instances are not available in the AWS Free Usage Tier program.

You will often pay less per hour than your maximum bid price. The Spot Price is adjusted periodically as requests come in and the available supply of instances changes. Everyone pays that same Spot Price for that period regardless of whether their maximum bid price was higher, and you will never pay more than your hourly maximum bid price.

Getting Started with Spot Instances

In this section, you will get started using Spot Instances. You'll walk through what you need to know before you begin and the prerequisites you need to get started. You'll learn about the tools you will use for specific Spot Instance tasks, and then you'll step through the main tasks.

If you are new to Spot Instances, take a look at Prerequisites for Using Spot Instances (p. 123) to make sure you can take full advantage of the benefits of this Amazon EC2 product. If you have been using Amazon EC2 and you're ready to proceed, click one of the items in the following list to get going.

Topics

• Prerequisites for Using Spot Instances (p. 123)
• Using the AWS Management Console for Spot Instances (p. 123)
• Using the AWS CLI and the EC2 CLI Tools for Spot Instances (p. 124)
• Using AWS Java SDK for Spot Instances (p. 125)
• Viewing Spot Instance Pricing History (p. 125)
• Creating a Spot Instance Request (p. 127)
• Finding Running Spot Instances (p. 130)
• Canceling Spot Instance Requests (p. 132)

Before requesting a Spot Instance, consider configuring your Amazon Machine Image (AMI) so that your application does the following tasks:

• Automatically performs the tasks you want at start-up because the instance will start asynchronously without notification. For example, if you're using batch processes, you could set up your AMI to pull jobs from an Amazon Simple Queue Service (Amazon SQS) queue.
• Stores important data regularly in a place that won’t be affected by instance termination. For example, you could store your data using Amazon Simple Storage Service (Amazon S3), Amazon SimpleDB, or Amazon Elastic Block Store (Amazon EBS).

Important

Although Spot Instances can use Amazon EBS-backed AMIs, be aware that you can't stop and start Spot Instances launched from an AMI that has an Amazon EBS root device. For information about Amazon EBS, see Amazon Elastic Block Store (Amazon EBS).

• Handles termination gracefully.
For information about creating AMIs, see Creating Your Own AMI (p. 49).

**Prerequisites for Using Spot Instances**

To work with Amazon EC2 Spot Instances, read and complete the instructions described in Getting Started with Amazon EC2 Linux Instances (p. 24), which provides information on creating your Amazon EC2 account and credentials.

In addition, there are a variety of tools you can use to work with Spot Instances. Whichever you choose—the AWS Management Console, the AWS Command Line Interface (AWS CLI), the Amazon EC2 command line interface (EC2 CLI), or the Amazon EC2 application programming interface (EC2 API)—you will have specific tools for assessing Spot price history, submitting Spot Instance requests (also called bids), and managing your Spot requests and instances. You can also use, develop, and manage your applications using the AWS SDKs. For more information, see Tools for Amazon Web Services.

In this topic, you get an overview of the AWS Management Console, and the AWS CLI and Amazon EC2 CLI tools available for Spot Instances. We assume that you have read and completed the instructions described in the following guides. They walk you through setting up your environment for use with the tools:

- AWS Management Console—Getting Started with AWS Management Console
- AWS CLI—AWS Command Line Interface User Guide
- Amazon EC2 CLI—Setting Up the Amazon EC2 Tools

For information about using the Amazon EC2 API, see Making API Requests (p. 664). For information about API actions, see the Amazon Elastic Compute Cloud API Reference.

**Using the AWS Management Console for Spot Instances**

In the AWS Management Console, the EC2 console has tools specifically designed for Spot Instance request tasks. The EC2 console also has general tools that you can use to manage the instances launched when your requests are fulfilled.

- The **Spot Requests** page is the main way you interact with your Spot Instance requests.

- **Spot Instance Pricing History** gives you an insight in the pricing patterns for specific Spot Instance types in Availability Zones over a defined period.
• Use the **Request Spot Instances** page to submit a Spot Instance request and specify the details of the instance to be launched when your request succeeds.

• Use the **Instances** page to manage the instances launched when your Spot request succeeds.

### Using the AWS CLI and the EC2 CLI Tools for Spot Instances

The AWS CLI and the Amazon EC2 CLI tools have commands that are specifically designed for managing Spot requests. The following table lists the commands you use for Spot request tasks. To manage the instances launched when your Spot request is fulfilled, use the same commands that you use for On-Demand EC2 instances.

### Using AWS Java SDK for Spot Instances

Java developers can go to the [AWS SDK for Java](https://docs.aws.amazon.com/sdk-for-java-v1/api/index.html) to consult the Java tutorials on Spot Instances:

- Tutorial: Amazon EC2 Spot Instances (p. 172)
- Tutorial: Advanced Amazon EC2 Spot Request Management (p. 180)

### Viewing Spot Instance Pricing History

The Spot Price represents the price above which you have to bid to guarantee that a single Spot request is fulfilled. When your bid is above the Spot Price, your Spot Instance is launched, and if the Spot Price rises above your bid price, your Spot Instance is terminated. You might choose to bid above the current Spot Price so that your Spot request is fulfilled quickly. However, before specifying a price with which you want to bid for your Spot Instance, we recommend that you view the Spot Price history. You can view the Spot Price history for the last 90 days for any pool of Spot Instances sharing the same instance type, operating system, and Availability Zone.

For example, let's say you want to bid on a Linux/UNIX t1.micro instance to be launched in the us-east-1 region. To view past prices in this Spot pool, specify these values using the Spot Instance Pricing History page of the AWS Management Console, the DescribeSpotPriceHistory API action, or `ec2-describe-spot-price-history` CLI command. If you need to launch your Spot Instance in a specific Availability Zone, you can specify that Availability Zone when retrieving the Spot Price history.

After you review the Spot Price history, you might choose to bid at a price that would have given you 75 percent Spot Instance uptime in the past. Or, you might choose to bid two times the current Spot Price because doing so would have given you 99 percent uptime in the past. However you frame your bid, keep in mind that past performance of Spot Prices is not a guarantee of future results. Spot Prices vary based on real-time supply and demand conditions, and the conditions that generated certain Spot Prices or pricing patterns in the past may not repeat themselves in the future.

**Note**

Make sure you have set up the prerequisites for working with Amazon EC2. If you haven't, see Prerequisites for Using Spot Instances (p. 123).

If you are using an API version earlier than 2011-05-15, the DescribeSpotPriceHistory action or the `ec2-describe-spot-price-history` command will return the lowest price across the region for the given time period and the prices will be returned in chronological order.
AWS Management Console

To view Spot Price history

1. From the Amazon EC2 console, click Spot Requests in the navigation pane.

   The Spot Requests pane opens on the right. It will list your Spot requests if you have any.

2. At the top of the pane, click Pricing History.

   The console displays the Spot Instance Pricing History page.

3. If you want to view the Spot Price history for specific Availability Zones, click the Availability Zone list and select an Availability Zone.

   The Spot Instance Pricing History page displays the Spot Instance pricing history for all zones or the zone you selected.

4. To view Spot pricing details, move your cursor across the graph to specific points in time. A vertical line follows the movement of your cursor, and the table below the graph displays the Spot prices for different Availability Zones and the date and time pointed to by your cursor and the vertical line.

5. Using the price history as a guide, select a price that you think would likely keep your instances running for the period of time you need.

Amazon EC2 Command Line Interface (CLI) Tools

To view Spot Price history

1. Enter the following command:

   $ ec2-describe-spot-price-history -H --instance-type m1.xlarge

Amazon EC2 returns output similar to the following:

<table>
<thead>
<tr>
<th>SPOTINSTANCEPRICE</th>
<th>Date</th>
<th>Instance Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.384000</td>
<td>2011-05-25T11:37:48-0800</td>
<td>m1.xlarge</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Windows us-east-1a</td>
</tr>
<tr>
<td>0.384000</td>
<td>2011-05-25T11:37:48-0800</td>
<td>m1.xlarge</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Windows us-east-1d</td>
</tr>
</tbody>
</table>
In this example, the price for the m1.xlarge instance type ranges between $0.242 and $0.384.

2. Using the price history as a guide, select a price that you think would likely keep your instances running for the period of time that you need.

Tip
You can filter the Spot history data so it includes only instance types or dates of interest to you. For more information about how to filter the results, go to ec2-describe-spot-price-history in the Amazon Elastic Compute Cloud Command Line Reference.

Viewing Spot Price History Using the API
To view the Spot Price history using the API, use the DescribeSpotPriceHistory action.

What do you want to do next?
- Creating a Spot Instance Request (p. 127)
- Finding Running Spot Instances (p. 130)
- Launching Spot Instances in Amazon Virtual Private Cloud (p. 165)

Creating a Spot Instance Request
After deciding on your bid price, you are ready to request a Spot Instance. Using the AWS Management Console, the API, or the CLI, you can specify how many Spot Instances you’d like, what instance type to use, and the bid price you are willing to pay.

If you request multiple Spot Instances at once, Amazon EC2 creates separate Spot Instance Requests with unique IDs (e.g., sir-1a2b3c4d) so that you can track the status of each request separately. For information about tracking Spot requests, see Tracking Spot Requests with Bid Status Codes (p. 138).

In this section, we discuss how to create requests for Amazon EC2 Spot Instances using the AWS Management Console or the CLI. To create a Spot Instance request using the API, use the RequestSpotInstances action. For more information about requesting Spot Instances, see the following:

- Spot Instance Limits (p. 135)
- Types of Spot Instance Requests (p. 137)
- Launching Spot Instances in Launch Groups and Availability Zones (p. 137)
- Spot Instance Request States (p. 136)
- Launching Spot Instances in Amazon Virtual Private Cloud (p. 165)

Note
Make sure you have set up the prerequisites for working with Amazon EC2. If you haven't, see Prerequisites for Using Spot Instances (p. 123).

AWS Management Console
To create a Spot Instance request

1. From the Amazon EC2 console, click Spot Requests in the navigation pane.
2. Click **Request Spot Instances**.

Except for the Spot Instance options that you specify to configure your Spot Instances, the process for requesting Spot Instances is the same as the process for launching On-Demand instances. You go through the same steps when you click **Launch Instance** from the **Instances** page: Choose an Amazon Machine Image (AMI) and an instance type, and configure the details of the instance. For information, see **Launch Your Instance** (p. 300).

3. On the **Configure Instance Details** screen, **Request Spot Instances** is checked as the **Purchasing Option** by default if you get to this configure screen from the **Spot Requests** page. It is only when the **Request Spot Instances** option is selected that the options related to Spot Instance requests are displayed.

![Configure Instance Details](image)

Specify the **Maximum price** you are willing to pay for your Spot Instance. This is a required option.

Notice that the current Spot Price for each of the Availability Zones in your region is listed. Use this information as a guide on the price to specify so that your request is fulfilled. Your instance launches and runs if your bid price exceeds the Spot Price.

**Note**
You cannot change the parameters of your Spot request, including the Spot price, after you’ve submitted the request.

To explore Spot Price trends, click **Pricing History** in the **Spot Requests** page. For information, see **Viewing Spot Instance Pricing History** (p. 125).

4. There are several details that you can define optionally. Select the options you want to define your Spot request and to configure your Spot Instance settings.

| **Request valid from** and **Request valid to** | Defines the validity period of a Spot request. The validity period, beginning with **Request valid from** through **Request valid to**, specifies the length of time that your request will remain valid. By default, a Spot request will be considered for fulfillment from the time it is created until it is either fulfilled or canceled by you. However, you can constrain the validity period using these options.  
**Note**  
The end time you specify doesn't apply to the Spot Instances launched by this request. This end time only applies to the Spot Instance request. |

5. Continue with the wizard as you normally would when launching instances. For information, see Launch Your Instance (p. 300).

If your request specified multiple instances, Amazon EC2 creates a separate Spot Instance request for each instance. The requests are displayed on the Spot Requests page.

---

**Amazon EC2 Command Line Interface (CLI) Tools**

To create a Spot Price request

- Enter the following command:

```
$ ec2-request-spot-instances
    --price price
    --user-data data
    --instance-count count
    --type one-time | persistent
    [--valid-from timestamp]
    [--valid-until timestamp]
    [--launch-group launchgroup]
    (run-instances-arguments)
```
For example:

```
$ ec2-request-spot-instances --price 0.32 ami-1234abcd --key MyKeypair --
group websrv --instance-type m1.small --instance-count 10 --type one-time
```

Amazon EC2 returns output similar to the following:

```
SPOTINSTANCEREQUEST    sir-09fb0a04    0.32    one-time        Linux/UNIX
open     2010-04-06T10:03:09+0200   ami-1234abc     m1.small
MyKeypair     websrv      monitoring-disabled
...
```

If your request specified multiple instances, Amazon EC2 creates a separate Spot Instance request for each instance; each instance has a different ID (e.g., sir-09fb0a04).

### Requesting Spot Instances Using the API

To request Spot Instances using the API, use the RequestSpotInstances action.

### Finding Running Spot Instances

Your Spot request will launch a Spot Instance when the Spot Price is below your bid price. A Spot Instance will run until either its maximum bid price is no longer higher than the Spot Price or you terminate the Spot Instance yourself. (If your bid price is exactly equal to the Spot Price, there is a chance your Spot Instance will remain running.) When your Spot request is fulfilled and has running instances, your Spot request will be active (as opposed to open, closed, or canceled). In this section, we describe how to find running Spot Instances associated with your active Spot requests.

**Note**

Make sure you have set up the prerequisites for working with Amazon EC2. If you haven’t, go to Prerequisites for Using Spot Instances (p. 123).

### AWS Management Console

To find running Spot Instances

1. From the Amazon EC2 console, click Instances in the navigation pane.

   The console displays a list of running instances.
2. To identify which of the instances were launched as a result of Spot requests, match the Instance IDs in the `Instances` page—where the `Lifecycle` column lists the instance as *spot*—with Instance IDs in the `Spot Requests` page. (You might need to turn on the display of the column by clicking `Show/Hide` in the top right corner.)

### Amazon EC2 Command Line Interface (CLI) Tools

#### To find running Spot Instances

1. Use `ec2-describe-spot-instance-requests`. If your Spot Instance request has been fulfilled (an instance has been launched), the instance ID appears in the response.

   ```bash
   $ ec2-describe-spot-instance-requests
   SPOTINSTANCEREQUEST  sir-e1471206  0.09  one-time  Linux/UNIX
   active  2010-09-13T16:50:44-0800
   i-992cf7dd  ami-813968c4  m1.small  MyKey  default
   monitoring-disabled
   ```

2. Alternatively, you can use `ec2-describe-instances` with the following filter: `--filter instance-lifecycle=spot`. If you’re using the command line interface tools on a Windows system, you might need to use quotation marks (`--filter "instance-lifecycle=spot"`). For more information about filters, see `Listing and Filtering Your Resources (p. 607)`.

   ```bash
   $ ec2-describe-instances --filter instance-lifecycle=spot
   Amazon EC2 returns output similar to the following:
   ```

   ```
   RESERVATION  r-b58651f1  111122223333  default
   INSTANCE  i-992cf7dd  ami-813968c4  ec2-184-72-8-111.us-west-1.compute.amazonaws.com  ip-10-166-105-139.us-west-1.compute.internal

• Tagging Spot Instance Requests (p. 144)
• Subscribe to Your Spot Instance Data Feed (p. 168)

Canceling Spot Instance Requests

If you no longer want your Spot request, you can cancel it. You can only cancel Spot Instance requests that are open or active. Your Spot request is open when your request has not yet been fulfilled and no instances have been launched. Your Spot request is active when your request has been fulfilled, and Spot Instances have launched as a result. If your Spot request is active and has an associated running Spot Instance, canceling the request does not automatically terminate the instance: You must terminate the running Spot Instance manually.

Note

Make sure you have set up the prerequisites for working with Amazon EC2. If you haven't, go to Prerequisites for Using Spot Instances (p. 123).

Your Spot request can be in other states in addition to open and active. For more information, see Spot Instance Request States (p. 136). You can then track the status of each of the requests separately. For information about tracking Spot requests, see Tracking Spot Requests with Bid Status Codes (p. 138).

A persistent Spot request will try to relaunch a Spot Instance whenever it is interrupted or terminated. If you want to end both the Spot request and its Spot Instance, make sure you cancel the Spot request before you terminate the Spot Instance to ensure that the request doesn’t launch a new instance.

AWS Management Console

To cancel Spot Instance requests

1. From the Amazon EC2 console, click Spot Requests in the navigation pane.

   The console displays a list of Spot Instance requests.

2. Select the Spot requests you want to cancel and click Cancel.

3. If you don’t want the associated Spot Instances to continue running, you can cancel them. Select them in the Instances page, then right-click and select Terminate.
Amazon EC2 Command Line Interface (CLI) Tools

To cancel Spot Instance requests

1. Enter the following command to see your Spot Instance requests:

```
$ ec2-describe-spot-instance-requests
```

Amazon EC2 returns output similar to the following:

```text
SPOTINSTANCEREQUEST    sir-09fb0a04    0.04 one-time    Linux/UNIX    closed
2010-04-06T10:03:09+0200    ami-b232d0db    m1.small    gsg-keypair    default
monitoring-disabled
```

2. To cancel the request, enter the following:

```
$ ec2-cancel-spot-instance-requests sir-09fb0a04
```

Amazon EC2 returns output similar to the following:

```text
SPOTINSTANCEREQUEST    sir-09fb0a04    canceled
```
3. To terminate the instances associated with the Spot request you just canceled, enter the following:

```bash
$ ec2-terminate-instances i-48cd4829
```

Amazon EC2 returns output similar to the following:

```
INSTANCE     i-48cd4829    running shutting-down
```

**Tip**
You can filter the list of Spot Instance requests to return only certain EC2 instance types. For more information about how to filter the results, go to `ec2-describe-spot-instance-requests` in the *Amazon Elastic Compute Cloud Command Line Reference*.

### Fundamentals of Spot Instances

If your application can tolerate interruptions and can handle dynamically changing compute capacity and prices, Amazon EC2 Spot Instances can be a powerful tool for optimizing your application’s costs and increasing its computational scale. Because Spot Instances are often offered at a large savings compared to regular On-Demand instances, you might be able to take advantage of Spot Instances to both accelerate your computational job and lower its overall cost.

This section presents the basics you need to know so you can create successful Spot requests, manage Spot Instances effectively, and plan for contingencies such as interruptions and changes in capacity.

- A Spot Instance request (also called a **bid**) defines the kind of Spot Instances you want and the maximum price you’re willing to pay for them. How you specify your bid determines the fulfillment of the request and the successful launch of Spot Instances. For information, see Placing Spot Requests (p. 135).

- You can use tags to manage your Spot Instances. For information, see Tagging Spot Instance Requests (p. 144).

- The interactions between Spot Price, available Spot capacity, and your bid price affect how long your Amazon EC2 Spot Instances run and when they get interrupted. For information, see Understanding Spot Instance Provisioning, Pricing, and Interruption (p. 145).

- The availability of Spot Instances varies significantly depending on Amazon EC2 capacity. When you use Spot Instances, you should expect and plan for interruptions and mitigate their effect on your applications. For information, see Protecting Your Spot Instance Data Against Interruptions (p. 147).

For product and pricing information, see the following pages:

Placing Spot Requests

The Spot Instance request (or bid) is a core element in Amazon EC2 Spot Instances. Your specifications for a Spot request—price, Availability Zone, launch group, and schedule—affect the fulfillment of the request and the successful launch of Spot Instances.

**Note**
You cannot change the parameters of your Spot request, including the Spot price, after you’ve submitted the request.

This section discusses the bid fundamentals you need to know to help you manage your Spot requests.

- **Spot Instance Limits (p. 135)**
  Discusses the two categories of limits when using Spot Instances: Spot bid price limits and Spot Instance request limits per region.
- **Customizing Your Spot Requests (p. 136)**
  Discusses the options you can specify to customize your Spot request.
- **Tracking Spot Requests with Bid Status Codes (p. 138)**
  Discusses Spot bid status information and how you can use it to understand what is going on with your Spot requests.

Depending on how quickly you want your Spot request fulfilled and how long you want your Spot Instances to continue running, there are a number of factors you need to consider when you bid on Spot Instances. The requirements you include in your Spot request can affect the chances that it will be fulfilled. If you have a number of requirements that must be met, your request can take longer to fulfill.

The maximum Spot Instance price you’re willing to pay—your bid price—may also affect how long your Spot Instances will run. If you want your instances to run as long as possible and have a low probability of interruption, you might consider submitting a higher bid price. If you are less concerned about Spot interruptions and simply want to take advantage of Spot cost savings, you should submit a lower bid price.

Your bid price is not necessarily the price that you pay. For example, if you bid $0.500, and the Spot Price is $0.300 per hour for the period, you only pay $0.300 per hour. If the Spot Price drops, you pay less. If the Spot Price increases, you pay the new price up to your bid price. If the Spot Price rises above your bid price (or another capacity constraint is encountered), your Spot Instance is interrupted.

**Note**
Bidding high does not guarantee that your Spot Instance won’t be interrupted. Also, do not assume that the Spot Price can never remain high for long periods of time. If Spot supply is tight for an extended period of time, the Spot Price can be elevated for a sustained period of time, pegged to the bid price of the highest bidders.

For information about creating Spot Instance requests, see [Creating a Spot Instance Request (p. 127)](#).

**Spot Instance Limits**

When you work with Spot Instances, there are two kinds of limits to consider: bid price limits and request limits.

- A Spot **Bid Price** limit is the maximum price you can bid when you make a request for Spot Instances.
- A Spot **Request** limit is the number of instances per region that you can request.
Spot Bid Price Limits

Starting on December 20, 2013, Amazon EC2 introduced a default limit on the maximum amount that you can bid for a Spot Instance. The default bid price limit is designed to protect Spot Instance customers from incurring unexpected charges due to high bid prices. The limit also aims to reduce the likelihood that Spot Prices rise to excessively high levels.

The default bid limit will be set to four times the On-Demand price. For example, if you submit a Spot Instance request for a Linux m3.2xlarge instance in us-east-1, for which the On-Demand price is $0.900 per hour, you may bid up to $3.600 per hour.

Note
If you currently have a bid above the new default limit, we recommend that you cancel your existing bid, and start bidding within the limits before December 20, 2013. After that date, Spot Instance requests that exceed your account’s bid limit may not be processed.

If your application requires you to bid above the default bid price limit, please submit a limit increase request to spot-limit-increase@amazon.com. Your limit increase request must include the following information:

- Your AWS account number.
- How you use Spot Instances and manage Spot interruptions.
- The bid price limit you are requesting (specifying the instance type, region, and product platform).

For information about On-Demand instance pricing, see Amazon EC2 Pricing.

Spot Request Limits

By default, you are limited to a total of 5 Spot Instance requests in a region. New AWS accounts might have lower limits. Currently, the instance types I2 and HS1 are not available on Spot. Also, some instance types are not offered in all regions. (For information about instance types, see Instance Types (p. 97).)

If you need to make additional Spot requests in a region, complete the Amazon EC2 instance request form. Specify in the Use Case Description that you are requesting an increase to your account’s Spot Instance request limit. Limit increases apply to the region specified in the request form.

Note
Keep in mind that even if you are within your Spot request limits, your Spot Instances can be terminated if your bid price no longer exceeds the Spot price, or if there is a Spot capacity shortage.

Customizing Your Spot Requests

You can use a number of options to customize your Spot requests so you get instances that address your needs. These options are discussed in the following topics:

- Types of Spot Instance Requests (p. 137)
- Launching Spot Instances in Launch Groups and Availability Zones (p. 137)

The options you choose can affect the success of your Spot requests as well as the lifespan of the Spot Instances that these requests launch.

Spot Instance Request States

A Spot Instance request can be in one of the following states:

- Open—The request is not fulfilled.
- Active—The request is currently active (fulfilled) and has an associated Spot Instance.
• **Failed**—The request failed because bad parameters were specified.

• **Closed**—The request either completed (a Spot Instance was launched and subsequently was interrupted or terminated), or was not fulfilled within the period specified.

• **Canceled**—The request is canceled because one of two events took place: You canceled the request, or the bid request went past its expiration date.

Depending on conditions, an instance might still be running even if the request is closed or canceled.

The *valid until* option that you specify when you submit a Spot Instance request applies only to the *request*; this deadline doesn’t apply to Spot Instances that are *launched* by the request. This means that when your Spot Instance request is canceled, either because the request went beyond its expiration date or because you manually canceled it, the Spot Instances that were launched previously through the now-canceled request don't automatically get terminated. The Spot Instance service will terminate a running instance only when the Spot Price equals or exceeds your price. However, you can always terminate your instances manually.

You can track the status of your Spot Instance requests as well as the status of the instances launched through bid status codes. For information about tracking Spot requests, see Tracking Spot Requests with Bid Status Codes (p. 138).

**Types of Spot Instance Requests**

You can make two types of Spot Instance requests—a one-time request or a persistent request. A one-time request remains active until one of the following conditions is met: All of the requested instances launch, the request expires, or you cancel the request. For example, if you create a one-time request for three instances, the request is considered complete after all three instances launch.

Persistent Spot Instance requests remain active until they expire or you cancel them, even if the requests were previously satisfied. For example, if you create a persistent Spot Instance request for one instance when the Spot price is $0.300, Amazon EC2 launches and keeps your instance running if your maximum bid price is above $0.300. If the Spot price rises above your maximum bid price and consequently your Spot Instance is terminated, your Spot Instance request remains active and Amazon EC2 will launch another Spot Instance for you when the Spot price falls below your maximum bid price.

With both one-time and persistent requests, instances continue to run until they no longer exceed the Spot Price, you terminate them, or the instances terminate on their own. If the maximum price is exactly equal to the Spot Price, an instance might or might not continue running (depending on available capacity).

**Launching Spot Instances in Launch Groups and Availability Zones**

You can opt to have your Spot Instances launch at the same time or in the same Availability Zone.

If you want Amazon EC2 to launch the instances in your Spot Instance request only if all of them can be fulfilled together, specify a *launch group* in your Spot Instance request. If you want to launch your instances together in a single Availability Zone, specify an *Availability Zone group*. You can select or specify these options using any of the following tools:

- The **Request Spot Instances** wizard in AWS Management Console
- The `aws ec2 request-spot-instances` AWS CLI command
- The `ec2-request-spot-instances` Amazon EC2 CLI command
- The **RequestSpotInstances** Amazon EC2 API action

However, although these options can be useful, implement them only when you need them. These options are requirements that can lower the chances that your Spot Instance requests are fulfilled.

**Using the Launch Group Option**
To tell Amazon EC2 to launch your instances only if all the instances in the Spot Instance request can be fulfilled, specify a Launch Group in your Spot Instance request using the AWS Management Console, the --launch-group option using the AWS CLI and Amazon EC2 commands, and the LaunchGroup option using the Amazon EC2 API action.

Keep in mind that specifying a launch group increases the chance that your Spot Instances will be terminated. When one instance in the launch group is terminated by the Spot service—for example, the Spot price rises above your bid price—all of the instances in the group are terminated.

**Note**

Launch group is a feature recognized and managed by the Spot service. If one or more instances in a launch group is terminated by you or a service other than Spot, the other instances in the launch group will not be terminated.

**Using the Availability Zone Group Option**

To tell Amazon EC2 to launch your instances in one Availability Zone, specify an Availability Zone group in your Spot Instance request using the AWS Management Console, the --availability-zone-group option using the AWS CLI and Amazon EC2 commands, and the AvailabilityZoneGroup option using the Amazon EC2 API action.

To identify a bid price for a Spot Instance in a specific Availability Zone, see Viewing Spot Instance Pricing History (p. 125) for the price over time in the Availability Zone where you want to make your bid. You will see the price history for the specified Availability Zone with the most recent set of prices listed first. If you don't specify an Availability Zone, you will get the lowest prices across all Availability Zones for the time period, starting with the most recent set of prices.

**Note**

The describe Spot price history commands return two pieces of data: the prices of the instance types within the time range that you specified and the time when the price changed, all within the specified Availability Zone group. The price is valid within the time period that you specified; the response merely indicates the last time that the price changed.

When you use the Amazon EC2 API action (DescribeSpotPriceHistory) or the Amazon EC2 CLI command (ec2-describe-spot-price-history) before the 2011-05-15 API version, you will get the lowest price across the region for the given time period and the prices will be returned in chronological order—that is, from the oldest to the most recent.

When you review Spot prices, remember that past performance is not a guarantee of future results. Spot prices vary based on real-time supply and demand conditions, and the conditions that generated certain Spot prices or pricing patterns in the past may not repeat themselves in the future.

For more information about Availability Zones, see Region and Availability Zone Concepts (p. 7).

**Tracking Spot Requests with Bid Status Codes**

**Topics**

- Life Cycle of a Spot Request (p. 139)
- Spot Bid Status Code Reference (p. 142)

Bid statuses can help you track your Amazon EC2 Spot Instance requests, plan your use of Spot Instances, and bid strategically. Spot bid status information is composed of a status code, the update time, and a status message. Together, they help you determine the disposition of your Spot request. For example, a bid status can tell you the reason why your Spot request isn't fulfilled yet or list the constraints that are impeding the fulfillment of your Spot request.

**Note**

A bid is a request that is conditionally tied to a price. The terms are used interchangeably in this documentation.
You can use any of the Amazon EC2 Spot Instance tools to obtain status information about your Spot requests. Spot bid status information will be available for new Spot requests as well as bid requests that you already have open. However, if you're using either the Amazon EC2 CLI or API tools to obtain bid status information, you need to use version 2012-10-01 or later of the API tools. The following table summarizes how you can get bid status information using the Amazon EC2 tools.

**Life Cycle of a Spot Request**

This diagram shows you the paths your Spot request can follow throughout its life cycle. Following the diagram, we explain each step of the life cycle—from making a request to the terminal state.

When you request a Spot Instance, your request goes through an evaluation process. At each step of the process—also called the Spot request *life cycle*—specific events dictate successive request states. In the life cycle diagram, each step is depicted as a node, and each node’s status code describes the status of your Spot request and Spot Instance.
1. **Pending evaluation** – As soon as you make your Spot Instance request, it goes into the pending-evaluation state.

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Request State</th>
<th>Instance State</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending-evaluation</td>

</tr>
</tbody>
</table>

The only reason your Spot bid request does not proceed to this pending-evaluation state is that at least one of the parameters is invalid (bad-parameters).

<thead>
<tr>
<th>Status Code</th>
<th>Request State</th>
<th>Instance State</th>
</tr>
</thead>
<tbody>
<tr>
<td>bad-parameters</td>
<td>closed</td>
<td>(none)</td>
</tr>
</tbody>
</table>

2. **Pending evaluation holding state** – Your Spot Instance request will report a status code in the holding state if one or more options you specified are valid but not met, or if we encounter a Spot capacity constraint. The options defined by your request affect the likelihood of it being fulfilled. For example, if you specified a max bid price below the current Spot Price, or requested that your Spot Instances be launched together in one Availability Zone, your Spot request will stay in a holding state until the Spot Price goes below your bid or the Availability Zone constraint is met.

The following table lists the status codes reported when your bid is in a holding state waiting for a constraint to be met.

<table>
<thead>
<tr>

</tr>
<tr>

</tr>
</tbody>
</table>

3. **Pending evaluation/fulfillment terminal state** – Before your request reaches the pending fulfillment phase, your Spot Instance request may end up in a terminal state if the valid dates you specified for the bid expired, you canceled the bid yourself, or a system error occurred.

**Note**
A canceled Spot request does not necessarily mean that the Spot Instance is terminated. In contrast, a closed Spot request means the request will no longer be considered and the Spot Instance is terminated.
The following table lists the status codes reported when your bid ends up in the *terminal* state after pending evaluation or pending fulfillment.

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Request State</th>
<th>Instance State</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule-expired</td>

<td>(none)</td>
</tr>
<tr>

</tr>
<tr>
<td>bad-parameters</td>
<td>failed</td>
<td>(none)</td>
</tr>
<tr>
<td>system-error</td>
<td>closed</td>
<td>(none)</td>
</tr>
</tbody>
</table>

* This status results from a cancellation initiated by a user.

4. **Pending fulfillment** – When the constraints you specified (if any) are met, and your bid price is equal to or higher than the current Spot Price, your Spot request goes into the *pending-fulfillment* state.

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Request State</th>
<th>Instance State</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending-fulfillment</td>
<td>open</td>
<td>(none)</td>
</tr>
</tbody>
</table>

At this point, the Amazon EC2 Spot service is getting ready to provision the instances that you requested. If the process stops at this point, it would likely be due to cancellation by the user before a Spot Instance was launched, or an unexpected system error (see *Pending evaluation/fulfillment terminal state*).

5. **Fulfilled** – When all the specifications for your Spot Instance are met, your Spot request is fulfilled. The Amazon EC2 Spot service launches the Spot Instance, which may take a few minutes.

</tbody>
</table>

At this point, your instance launches, and your bid request is active. Your instance will continue to run as long as your bid price is at or above the Spot Price, Amazon EC2 has spare Spot capacity for your instance type, and you don't terminate the instance.

**Note**

If your bid price is equal to the market price, your request can stay fulfilled, but you run the risk of your Spot Instance getting terminated at any time that the market price goes up. In some cases, your Spot Instance could be evicted even if your bid equaled the Spot Price because Spot Instances were oversubscribed at that price. In such cases, you will get the *instance-terminated-capacity-oversubscribed* status code. For more information, see *Fulfilled terminal state*.

6. **Fulfilled terminal state** – Your Spot request will report a status code in the *terminal* state if a change in Spot Price or capacity requires the Spot service to terminate your Spot Instance. You will also get a terminal state status code if you cancel the Spot request or terminate the Spot Instance.

The following table lists the status codes reported when your instance is in the *terminal* state after the bid was fulfilled.

</tbody>
</table>

[a] If the Spot bid request is persistent, the state of the request becomes open. See the next item, Persistent requests.

[b] If you terminate your instance first, there might be a delay before the Spot service detects that your Spot Instance was terminated. For persistent requests, this means that for user-terminated instances it could take some time before your Spot request re-enters the pending-evaluation state. With this status code, the request state can either be closed or canceled. Request state is closed if you terminate the instance, but keep your bid running. Request state is canceled if you terminate the instance and cancel the bid.

[c] Actions are initiated by the user.

7. Persistent requests – When your Spot Instances are terminated (either by you or the Amazon EC2 Spot service), if you specified a persistent Spot request, then the request will be considered again. This request returns to the pending-evaluation state. Your Spot bid request will undergo the same evaluation process that it originally went through, and an entirely new Spot Instance will be launched for the persistent Spot request.

Spot Bid Status Code Reference

The following list contains Spot bid status codes and explanations about what the code means for your Spot request:

• **az-group-constraint**

  The Spot service cannot launch all the instances you requested in the same Availability Zone.

• **bad-parameters**

  One or more of the parameters of your Spot request was invalid or malformed (for example, the AMI you specified may not exist). The bid status message will tell you which parameter is invalid.

• **canceled-before-fulfillment**

  The user canceled the Spot request before it was fulfilled.

• **capacity-not-available**

  There is no capacity available for the instances you requested.

• **capacity-oversubscribed**

  The number of Spot requests with bid prices equal to or higher than your bid price exceeds the available capacity in this pool.

• **constraint-not-fulfillable**
The Spot request cannot be fulfilled because one or more constraints are invalid. For example, you provided an invalid from or to or an invalid Availability Zone. The bid status message will tell you which constraint was invalid.

• fulfilled

Your bid request was fulfilled, so your Spot request is active, and the Amazon EC2 Spot service is launching (or has launched) your Spot Instance.

• instance-terminated-by-user (or spot-instance-terminated-by-user)

You terminated a Spot Instance that had been fulfilled, so the bid state becomes closed (unless it's a persistent bid), and the instance state is terminated.

  Note
  The status codes instance-terminated-by-user and spot-instance-terminated-by-user represent the same status. The code spot-instance-terminated-by-user will be deprecated.

• instance-terminated-by-price

The Spot Price rose above your bid price. If your request is a persistent bid, the process—or life cycle—restarts and your bid will again be pending evaluation.

• instance-terminated-capacity-oversubscribed

Your instance was terminated because the number of Spot requests with bid prices equal to or higher than your bid price has exceeded the available capacity in this pool. This means that your instance was interrupted even though the Spot Price may not have changed because your bid was at the Spot Price.

  Note
  When there are several requests at a certain bid price and only some of them need to be terminated, the Spot service randomly selects the requests to be terminated.

• instance-terminated-launch-group-constraint

One of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

• instance-terminated-no-capacity

There is no longer any Spot capacity available for the instance.

• launch-group-constraint

The Spot service cannot launch all the instances you requested at the same time.

  Note
  All requests in a launch group have their instances started and terminated together. For more information about using Launch Group in your Spot request, see Launching Spot Instances in Launch Groups and Availability Zones (p. 137).

• marked-for-termination

Your Spot Instance is marked for termination.

• not-scheduled-yet

Your Spot request will not be evaluated until the scheduled date.

• pending-evaluation

As soon as you make your Spot Instance request, it goes into the pending-evaluation state while the system evaluates the parameters of your request.

• pending-fulfillment
Your Spot request is pending fulfillment while the system tries to provision your Spot Instance.

- placement-group-constraint
  
  Your Spot request cannot be fulfilled yet because a new Spot Instance cannot currently be added to the placement group you specified.

- price-too-low
  
  You have a bid request that cannot be fulfilled because the bid price is below the Spot Price. In this case, no instance is launched, and your bid remains open.

- request-canceled-instance-running
  
  You canceled your Spot request while the Spot instance was still running, so the request is canceled, but the instance remains running.

- schedule-expired
  
  Your Spot request has expired because it was not fulfilled before the valid to date.

- system-error
  
  There was an unexpected system error. If this is a recurring issue, please contact customer support for assistance.

## Tagging Spot Instance Requests

To help categorize and manage your Spot Instance requests, you can tag them with metadata of your choice. You tag your Spot Instance requests in the same way that you tag other Amazon EC2 resources. Create a tag by specifying a key and value, and assign the pair to the Spot Instance request.

The tags you create for your Spot Instance requests only apply to the requests. These tags don’t propagate to the instances that the requests launch. When your request is fulfilled and a Spot Instance launches, the tag you used for your Spot Instance request is not applied to the Spot Instance. To categorize the Spot Instances that are launched from your tagged request, you must create a separate set of tags for the instances.

You can tag your Spot Instance request when you first create it, or you can assign a tag to the request after you create it. You can use the following tools to tag Spot Instance requests:

- The **Spot Requests** page of the EC2 console of the AWS Management Console
- `create-tags` AWS CLI command
- `ec2-create-tags` Amazon EC2 CLI command
- `CreateTags` API action

For information about tagging in Amazon EC2, see [Tagging Your Amazon EC2 Resources](p. 610).

### To create a tag for your Spot Instance request

1. When you create a Spot Instance request using the AWS Management Console, you first go through the steps of specifying your Amazon Machine Image (AMI) and instance type. For information, see [Creating a Spot Instance Request](p. 127).

   After you have specified the instance configuration and storage details, click **Next: Tag Instances**.

2. In the **Tag Spot Request** step, type the key name and value you want for the tag, and click **Review and Launch**.
If you want to create another tag, click **Create Tag**.

3. If you want to create a tag for a Spot Instance request that already exists, in the **Spot Requests** page, select the Spot request that you want to tag, then, in the bottom pane, go to the **Tags** tab, and click **Add/Edit Tags**.

In the **Add/Edit Tags** box, click **Create Tag**, type the key name and value you want for the tag, and click **Save**.

If you want to apply tags to Spot Instances that are launched from the Spot request that you just tagged, you must create a separate set of tags for the instances using the same tools and commands. For information about tagging instances, see **Tagging Your Amazon EC2 Resources** (p. 610).

**Understanding Spot Instance Provisioning, Pricing, and Interruption**

If you have Amazon EC2 Spot Instances, you will want to know how long your Spot Instances run, when they get interrupted, and how they are priced. These factors depend on the price you set for your bid, the Spot Price set by Amazon EC2, and the available Spot capacity. When you understand how these factors interact, you should be able to use Spot Instances more effectively.

- Supply and Demand in the Spot Market (p. 146)
- Understanding Interruptions (p. 147)

For pricing information, see **Amazon EC2 Spot Instances**.
Supply and Demand in the Spot Market

Spot Instances are spare EC2 instances made available at a price that varies with supply and demand. When you request a Spot Instance, you set the maximum price you are willing to pay (your bid). AWS continuously evaluates how much spare Amazon EC2 capacity in each instance pool can be offered on Spot, what bids have been made for each pool, and then provisions the available Spot capacity to the highest bidders. The Spot Price for the pool is set to the lowest fulfilled bid in that pool. (An instance pool is a group of instances that share the same region, Availability Zone, instance type, operating system, and network platform.) This means that, strictly speaking, the Spot Price is the price above which you have to bid to fulfill a Spot request for a single Spot Instance.

Here’s an illustration of how this Spot provisioning and pricing mechanism works.

Assume that you are bidding on a Spot pool (e.g., the us-east-1a region and Availability Zone, m1.small instance type, Linux operating system, and VPC network platform) that has only five Spot Instances for sale. Your bid price is $0.100, which is also the current Spot Price. The current bids have the following bid prices.

<table>
<thead>
<tr>
<th>Bid</th>
<th>Bid Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>$1.000</td>
</tr>
<tr>
<td>2.</td>
<td>$1.000</td>
</tr>
<tr>
<td>3.</td>
<td>$0.100</td>
</tr>
<tr>
<td>4.</td>
<td>$0.100</td>
</tr>
<tr>
<td>5.</td>
<td>$0.100</td>
</tr>
<tr>
<td></td>
<td>Last fulfilled bid sets the Spot Price</td>
</tr>
<tr>
<td></td>
<td>Spot capacity cutoff</td>
</tr>
</tbody>
</table>

Your bid is $0.100, which is also the current Spot Price. The current bids have the following bid prices.

Note
Bids are ranked in descending order. Bids that share the same bid price (tied bids) are ranked randomly.

In the table, bids 1-5 are fulfilled. Bid 5, being the last fulfilled bid, sets the Spot Price at $0.100. Bid 6 is unfulfilled. Bids 3-5, which share the same bid price of $0.100, are stacked in random order.

Now, let’s say that the spare Amazon EC2 capacity available to this Spot pool drops to 3. The Spot pool will now look like this:

<table>
<thead>
<tr>
<th>Bid</th>
<th>Bid Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>$1.000</td>
</tr>
<tr>
<td>2.</td>
<td>$1.000</td>
</tr>
<tr>
<td>3.</td>
<td>$0.100</td>
</tr>
<tr>
<td></td>
<td>Last fulfilled bid sets the Spot Price</td>
</tr>
<tr>
<td></td>
<td>Spot capacity cutoff</td>
</tr>
<tr>
<td>4.</td>
<td>$0.100</td>
</tr>
<tr>
<td>5.</td>
<td>$0.100</td>
</tr>
<tr>
<td></td>
<td>Your bid</td>
</tr>
</tbody>
</table>

In the table, bids 1-3 are fulfilled. Bid 4, being the last fulfilled bid, sets the Spot Price at $0.100. Bid 5 is unfulfilled. Bids 3-4, which share the same bid price of $0.100, are stacked in random order.
Bid Price

<table>
<thead>
<tr>
<th>Bid</th>
<th>Bid Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>$0.050</td>
</tr>
</tbody>
</table>

Bids 1-3 are fulfilled. Bid 3, the last fulfilled bid, sets the Spot Price at $0.100. Bids 4-5, which also are $0.100, are unfulfilled. As you can see, even though the Spot Price didn’t change, two of the $0.100 bids—Bid 4 (your bid) and Bid 5—have been interrupted because the Spot supply shrank.

If you still want to fulfill a Spot request for a single instance, you would have to bid above the current Spot Price of $0.100. If you bid $0.101, your Spot Instance would be fulfilled, Bid 3 would be interrupted and the Spot Price would become $0.101. If you bid $2.000, Bid 3 would be interrupted and the Spot Price would become $1.000 (Bid 2’s price). Keep in mind that, in the scenario above, no matter how high you bid, you could never get more than 3 instances fulfilled.

If spare Amazon EC2 capacity available to Spot dropped to zero, all bids would be interrupted.

Note

This means that your Spot Instance could be interrupted, no matter how high you bid. Never bid higher than you’re willing to pay because, when there is price competition in the Spot market—typically for a small amount of available Spot capacity—Spot Prices can rise unexpectedly and remain elevated for extended periods of time.

Understanding Interruptions

When you use Spot Instances, you must always be prepared for interruptions. Your instances can be interrupted at any time; they are not protected by a high Spot bid. Consequently, you must ensure that you have a backup system for your data. Instance data is not saved by default; it will be lost when the instance is interrupted.

There are three possible reasons why your Spot Instances get interrupted.

- **Spot Price**—If your bid price, which is the maximum price you’re willing to pay for a Spot Instance, is lower than the current Spot Price, your running Spot Instance will be terminated.

  Amazon EC2 sets a Spot Price for each instance type in each Availability Zone. The Spot Price is the price all customers will pay to run a Spot Instance for that given period. The Spot Price fluctuates based on supply and demand for instances, but customers will never pay more than the maximum price that they have specified in their Spot request. If the Spot Price moves higher than a customer’s maximum price, the customer’s instance will be shut down by Amazon EC2.

- **Capacity**—If there is not enough spare Amazon EC2 capacity, Spot Instances will be terminated, starting with those instances with the lowest bids. If there are several instances with the same bid price, the order of instance termination is determined at random.

- **Request constraints**—If you requested Spot Instances with constraints, such as the same launch group or the same Availability Zone group, these instances can be interrupted as a group if the constraint can no longer be met.

The cause of your Spot Instance’s interruption affects how you are charged. If you terminate your Spot Instance, you are charged for a full hour of usage regardless of whether you used it a full hour. If Amazon EC2 terminates your Spot Instance, you are not charged for the terminated hour. Your account is not charged until your request for a new Spot Instance is placed and your Spot Instance is launched.

Protecting Your Spot Instance Data Against Interruptions

Customer demand for Amazon EC2 Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how much Amazon EC2 capacity
is available. Therefore, it is always possible that your Spot Instance will be interrupted if another user bids higher than you or if we have to reclaim spare capacity.

**Note**

No matter how high you bid, there is always a risk that your Spot Instance will be interrupted. We strongly recommend against bidding above the On-Demand price or using Spot for applications that cannot tolerate interruptions.

The following sections discuss how to plan for and mitigate the impact of interruptions.

- Planning for Interruptions (p. 148)
- Persisting Your Root EBS Partition (p. 148)

### Planning for Interruptions

**Topics**

- Quick Look: Managing Interruptions Video (p. 148)

Because Spot Instances can terminate at any time, applications that run on Spot Instances must terminate cleanly. Although we attempt to terminate your instances cleanly, your application should be prepared to deal with an immediate shutdown.

To test your application, launch and terminate it as an On-Demand instance.

**Quick Look: Managing Interruptions Video**

The following video shows how some customers manage the interruption of their Spot instances. [How to Manage Spot Instance Interruptions](#)

For more information about strategies to manage interruptions, go to the following sections:

### Persisting Your Root EBS Partition

Amazon Elastic Block Store (Amazon EBS) can be an effective way to store data that you otherwise might lose when your Spot Instance terminates.

**Important**

Although Spot Instances can use Amazon EBS-backed AMIs, be aware that you can't stop and start Spot Instances launched from an AMI that has an Amazon EBS root device. For information about Amazon EBS, see [Amazon Elastic Block Store (Amazon EBS)](#).

To set up the persistence of Spot Instance data, you map the Spot Instances that will be launched to an existing Amazon Elastic Block Store (Amazon EBS) snapshot. Set the `delete-on-termination` flag to `false`; this indicates that Amazon EC2 shouldn't delete the Amazon EBS volume when the spot instance terminates.

Let's walk through making an example Spot request with the following specifications:

- Bid price of $0.500
- One instance of the m1.xlarge instance type
- Block device mapping to a snapshot that shouldn't be deleted when the Spot Instance is terminated
You can do this example using either the CLI or API tools. Using the CLI, your example request should look like this:

```
$ ec2-request-spot-instances -p 0.5 -t m1.xlarge -n 1 -b '/dev/sdb=snap-a123bcde:20:false' ami-8e1fece7
```

- Obtaining Information About the Instances Launched by Auto Scaling (p. 154)
- Updating the Bid Price for the Spot Instances (p. 158)
- Scheduling Spot Bid Requests (p. 161)
- Using Auto Scaling to Get Notifications for Spot Instances (p. 161)

You can take advantage of Auto Scaling features to manage your Amazon EC2 Spot Instances. With Auto Scaling, you can scale up or down your capacity based on demand by setting up Auto Scaling to make Spot bids on your behalf.

In addition, you can use Auto Scaling’s scheduling functionality for more granular control over when to bid and launch your Spot Instances. You also can use an Amazon Simple Notification Service (Amazon SNS)-backed Auto Scaling feature that sends notifications each time specified events—such as the launch or termination of instances—take place. Using Auto Scaling’s scheduled actions, you can set up bids to expire at a set time.

When you use Auto Scaling with Spot Instances, there are some Auto Scaling tools that you have to use instead of the Spot Instance tools that might be familiar. There are also a number of Spot Instance options that you cannot use. Here’s a summary of differences:
• **Setting your bid price.** When you use Auto Scaling to launch Spot Instances, you set your bid price in an Auto Scaling launch configuration.

• **Spot Price and your bid price.** This is the same as current behavior. If the market price for Spot Instances rises above your bid price for a running instance, Amazon EC2 will terminate your instance.

• **Changing your bid price.** If you want to change your bid price, you have to create a new launch configuration and associate it with your Auto Scaling group. You cannot update the existing launch configuration.

• **New bid price and running instances.** When you change your bid price by creating a new launch configuration, instances already launched will continue to run as long as the bid price for those running instances is higher than the current market price for Spot Instances.

• **Spot and Auto Scaling instance termination.** Amazon EC2 terminates a Spot Instance when the bid price for that instance falls below the Spot Price. Auto Scaling terminates instances based on a combination of criteria, including the launch configuration it is associated with, length of time in a billing hour the instance has been running, and the Availability Zone in which it is launched. For more information about instance termination in Auto Scaling, see [Auto Scaling Instance Termination](#).

• **Maintaining your Spot Instances.** When your instance is terminated, Auto Scaling will try to launch another instance to replace it in order to maintain your specified desired capacity. However, whether or not Auto Scaling successfully launches an instance depends on the bid price as compared to the Spot Price: If the bid price is higher than the Spot Price, then an instance will be launched; if the Spot Price is higher than the bid price, then no instance will be launched at that point.

• **Persistent bids.** Auto Scaling will continue submitting bids for you as long as you keep your Auto Scaling group and launch configuration. The Auto Scaling group specifies the desired number of instances you want maintained and the launch configuration specifies the bid price for your Spot Instances.

For more information about Auto Scaling, see [Auto Scaling Developer Guide](#). To get started quickly with Auto Scaling, see [Auto Scaling Getting Started Guide](#).

**Tools for Managing Auto Scaling with Spot Instances**

You will use the Auto Scaling command line interface (CLI) tools to use the Auto Scaling features with Spot Instances. Currently, the AWS Management Console does not have support to create and manage Auto Scaling objects. However, you can view most details about bids and Amazon EC2 instances launched by Auto Scaling on the AWS Management Console.

To use the Auto Scaling CLI tools, download and unzip the package, and set up the tools on your computer just as you set up your Amazon EC2 CLI tools. The Auto Scaling CLI tools and the Amazon EC2 CLI tools are shipped as different tools packages.

The following table lists resources that can help you get started with the Auto Scaling CLI tools. For more information, see [Auto Scaling Tools](#) in the [Auto Scaling Developer Guide](#).

To get help about Auto Scaling CLI commands

After you have installed the Auto Scaling CLI tools, you can get more information about the commands by querying the command line.

1. Open the Command Line.
2. Navigate to Install Drive\AutoScaling-n.n.n.bin.
3. Type `as-cmd` and press Enter.

The command line returns a list of Auto Scaling CLI commands and a short description of what each command does.

For example, here are some of the Auto Scaling CLI commands we will use in this section.

Launching Spot Instances with Auto Scaling

In this section, we will create an Auto Scaling launch configuration and an Auto Scaling group that launch Spot Instances. We will use the Auto Scaling command line interface (CLI) commands to create the
launch configuration and the Auto Scaling group, and to verify and obtain information about them and
the Amazon EC2 instances that they launch.

**Prerequisites**

If you’re not familiar with how to create a launch configuration or an Auto Scaling group, we recommend
that you go through the steps in the Basic Auto Scaling Configuration in the Auto Scaling Developer
Guide. Use the basic scenario to get started with the infrastructure that you need in most Auto Scaling
scenarios.

If you don’t have the Auto Scaling CLI tools installed on your computer, you must install them to do this
walkthrough. For information, see Tools for Managing Auto Scaling with Spot Instances in the Amazon
Elastic Compute Cloud User Guide. You can also use the information in Install the Command Line Interface
in the Auto Scaling Developer Guide.

In this scenario, we will perform the following tasks:

- Step 1: Create a Launch Configuration (p. 152)
- Step 2: Create an Auto Scaling Group (p. 153)

If you already have a launch configuration and Auto Scaling group, here are other related Spot Instance
tasks that you can do using Auto Scaling:

- Updating the Bid Price for the Spot Instances (p. 158)
- Scheduling Spot Bid Requests (p. 161)
- Using Auto Scaling to Get Notifications for Spot Instances (p. 161)
- Advanced Tasks (p. 168)

For more information about Auto Scaling, see What is Auto Scaling? in the Auto Scaling Developer Guide.

**Step 1: Create a Launch Configuration**

An Auto Scaling launch configuration is a template that contains the parameters necessary to launch new
Amazon EC2 instances. You can attach only one launch configuration to an Auto Scaling group at a time.
You have to create a launch configuration and then an Auto Scaling group in order to launch instances
with Auto Scaling.

To place bids for Spot Instances, use the `as-create-launch-config` Auto Scaling CLI command with
the `--spot-price` option. Specify the maximum price you want to pay for an instance. This price will
be used by Auto Scaling to bid for your instances, but this price is not necessarily what you pay for the
instances when they are launched. You will pay the Spot Price. For example, you bid $0.05 for m1.small
instances. Your bid gets fulfilled if the current market price for m1.small Spot Instance is $0.03, or any
other price below $0.05, and you will be charged the current price of $0.03 per hour. In fact, as long as
your current bid is higher than the market price, your bid will be fulfilled and a Spot Instance will be
launched for you.

You can get guidance on the price to bid by checking Spot Price history. You can do this by using the
AWS Management Console, CLI, or API. For more information, go to Viewing Spot Instance Pricing
History (p. 125).

The `as-create-launch-config` command takes the following arguments:

```
    as-create-launch-config LaunchConfigurationName --image-id value --instance-type
    value [--spot-price value] [--iam-instance-profile value] [--block-device-mapping
    "key1=value1,key2=value2..." ] [--monitoring-enabled|--monitoring-disabled]
    [--kernel value ] [--key value ] [--ramdisk value] [--group value [,value...]
    ] [--user-data value] [--user-data-file value] [General Options]
```
The only required options are the launch configuration name, image ID, and instance type. For this walkthrough, specify:

- **Launch configuration name** = `spotlc-5cents`

  **Note**
  When Auto Scaling launches instances, it does not distinguish the Spot Instances from the On-Demand instances. To help you identify which of your instances are Spot Instances, consider assigning a launch configuration name that includes `spot` and the bid price.

- **Image ID** = `ami-e565ba8c`

  The Image ID identifies the Amazon Machine Image (AMI) that will be used to launch the instances. If you don't have an AMI, and you want to find a suitable one, see Finding a Suitable AMI (p. 53).

- **Instance type** = `m1.small`

- **Spot Price** = `$0.05`

  This parameter is optional. If you want to launch Spot Instances, you must specify the Spot bid price that will be used to bid for Spot Instances. Spot Instance bid prices must be specified in US dollars.

Your command should look similar to the following example:

```
as-create-launch-config spotlc-5cents --image-id ami-e565ba8c --instance-type m1.small --spot-price "0.05"
```

You should get a confirmation like the following example:

```
OK-Created launch config
```

**Step 2: Create an Auto Scaling Group**

An Auto Scaling group is a collection of Amazon EC2 instances that shares similar characteristics and to which you want to apply certain scaling actions. You can use the Auto Scaling group to automatically scale the number of instances or maintain a fixed number of instances. You can attach only one launch configuration to an Auto Scaling group at a time. You have to create a launch configuration and then an Auto Scaling group in order to launch Amazon EC2 instances with Auto Scaling.

The `as-create-auto-scaling-group` command takes the following arguments:

```
```

This command requires that you specify a name for your Auto Scaling group, a launch configuration, one or more Availability Zones, a minimum group size, and a maximum group size. The Availability Zones you choose determine the physical location of your Auto Scaling instances. The minimum and maximum group size tells Auto Scaling the minimum and maximum number of instances the Auto Scaling group should have.

Desired capacity is an important component of the `as-create-auto-scaling-group` command. Although it is an optional parameter, desired capacity tells Auto Scaling the number of instances you want to run initially. To adjust the number of instances you want running in your Auto Scaling group, you change the value of `--desired-capacity`. If you don't specify `--desired-capacity`, its value is the same as minimum group size.
For more information on the syntax of the `as-create-auto-scaling-group` command, see Basic Auto Scaling Configuration in the Auto Scaling Developer Guide. You can also get help information from the command line: `as-create-auto-scaling-group --help`. For more information, see Resources for Using Auto Scaling CLI Tools (p. 150).

For this walkthrough, specify these values for the command:

- **Auto Scaling Group name** = `spotasg`

  **Note**
  When Auto Scaling launches instances, it does not distinguish the Spot Instances from the On-Demand instances. To help you identify which of your instances are Spot Instances, consider assigning Spot-specific names to the Auto Scaling group that launches Spot Instances.

- **Launch configuration name** = `spotlc-5cents`
- **Availability Zone** = `us-east-1a,us-east-1b`
- **Max size** = 5
- **Min size** = 1
- **Desired capacity** = 3

Your command should look like the following example:

```
as-create-auto-scaling-group spotasg --launch-configuration spotlc-5cents --availability-zones "us-east-1a,us-east-1b" --max-size 5 --min-size 1 --desired-capacity 3
```

You should get confirmation like the following example:

```
OK-Created AutoScalingGroup
```

### Obtaining Information About the Instances Launched by Auto Scaling

You can use the Auto Scaling CLI tools to obtain information about your launch configuration, Auto Scaling groups and Amazon EC2 instances launched by Auto Scaling.

In this section, we will use the following Auto Scaling CLI commands to get information about the Spot Price bids and Spot Instances that Auto scaling makes and launches for you.

- `as-describe-scaling-activities`—You can use the information about Auto Scaling activities that this command returns to check the status of the bids submitted for you by Auto Scaling.
- `as-describe-auto-scaling-groups`—You can use the information about Auto Scaling groups that this command returns to confirm that Auto Scaling is launching your Spot Instances according to your specifications.
To check the status of the bids that Auto Scaling is making for you

The `as-describe-scaling-activities` command lists the activities that Auto Scaling performed for a specified Auto Scaling group.

This is the basic syntax:

```
as-describe-scaling-activities [ActivityIds [ActivityIds ...]]
[--auto-scaling-group value] [--max-records value] [General Options]
```

Specifying the Auto Scaling group and the Activity ID are optional. If you don't specify the Auto Scaling group, the command will return all activities for all Auto Scaling groups associated with your account. If you specify the Auto Scaling group, only the activities for that Auto Scaling group will be listed.

In this scenario, we are using the `as-describe-scaling-activities` command to see state of your bid. Assume that there is only one Auto Scaling group (spotasg) and you want to list all activities.

1. Open a command line and navigate to the `bin` folder of your Auto Scaling CLI tools directory.
2. Type the command:

   `as-describe-scaling-activities --auto-scaling-group spotasg --headers`

The information you get should be similar to the following example:

<table>
<thead>
<tr>
<th>ACTIVITY</th>
<th>ACTIVITY-ID</th>
<th>END-TIME</th>
<th>GROUP-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTIVITY</td>
<td>31bcbb67-7f50-4b88-ae7e-e564a8c80a90</td>
<td></td>
<td>spotasg</td>
</tr>
<tr>
<td></td>
<td>WaitingForSpotInstanceId</td>
<td>Placed Spot instance request: sir-fc8a3014. Waiting for instance(s)</td>
<td></td>
</tr>
<tr>
<td>ACTIVITY</td>
<td>770bbeb5-407c-404c-a826-856f65db1c57</td>
<td></td>
<td>spotasg</td>
</tr>
<tr>
<td></td>
<td>WaitingForSpotInstanceId</td>
<td>Placed Spot instance request: sir-69101014. Waiting for instance(s)</td>
<td></td>
</tr>
<tr>
<td>ACTIVITY</td>
<td>597e4ebd-220e-42bc-8ac9-2bae4d20b8d7</td>
<td>2012-05-23T17:40:22Z</td>
<td>spotasg</td>
</tr>
<tr>
<td></td>
<td>Successful</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this response, you know that your bids were placed, one of the bids is successful, and Auto Scaling is waiting for the other two bids.

**Note**

If the `as-describe-scaling-activities` command returns a list that includes *Failed* activities, check the data you specified in the launch configuration. For example:

- The Amazon Machine Image (AMI) might not be valid anymore.
- The bid price specified in the launch configuration is lower than the Spot Price.

3. If you run the `as-describe-scaling-activities` command again later, you can be getting information that is similar to the following example:

<table>
<thead>
<tr>
<th>ACTIVITY</th>
<th>ACTIVITY-ID</th>
<th>END-TIME</th>
<th>GROUP-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTIVITY</td>
<td>90630906-b40f-41a6-967a-cd6534b2dfca</td>
<td>2012-06-01T02:32:15Z</td>
<td>spotasg</td>
</tr>
<tr>
<td></td>
<td>Successful</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ACTIVITY</td>
<td>a1139948-ad0c-4600-9efe-9dab8ce23615</td>
<td>2012-06-01T00:48:02Z</td>
<td>spotasg</td>
</tr>
<tr>
<td></td>
<td>Successful</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ACTIVITY</td>
<td>33001e70-6659-4494-a817-674d1b7a2f58</td>
<td>2012-06-01T02:31:11Z</td>
<td>spotasg</td>
</tr>
<tr>
<td></td>
<td>Successful</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The output shows that the listed activities were successful. Because we know that `spotasg` is an Auto Scaling group that uses a launch configuration with a spot bid price, you can assume that the activities represent the bids placed by Auto Scaling.

4. If you want to get more details about the activities and instances, use the `--show-xml` option of `as-describe-scaling-activities`. Enter the following command:

   ```bash
   as-describe-scaling-activities --auto-scaling-group spotasg --show-xml
   ```

   The information you get should be similar to the following example.

   ```xml

The XML output shows more detail about the Spot and Auto Scaling activity.

• Cause: At 2012-06-01T00:48:21Z a difference between desired and actual capacity changing the desired capacity, increasing the capacity from 2 to 3. Description: Launching a new EC2 instance: i-fe30d187

If an instance is terminated and the number of instances falls below the desired capacity, Auto Scaling will launch a new instance so that the total number of your running instances rises back to the level specified for desired capacity.

• Cause: At 2012-06-01T00:47:51Z an instance was taken out of service in response to a system health-check. Description: Terminating EC2 instance: i-88ce28f1

Auto Scaling maintains the desired number of instances by monitoring the health status of the instances in the Auto Scaling group. When Auto Scaling receives notification that an instance is unhealthy or terminated, Auto Scaling launches another instance to take the place of the unhealthy instance. For information, see Configure Health Checks for Your Auto Scaling group in the Auto Scaling Developer Guide.

Note
Auto Scaling provides the cause of instance termination that is not the result of a scaling activity. This includes instances that have been terminated because the Spot Price exceeded their bid price.

When Auto Scaling attempts to replace terminated instances resulting from the Spot Price rising above the instances’ bid price, Auto Scaling will place the bid specified in the current launch configuration and attempt to launch another instance to maintain the desired capacity.

To confirm that Auto Scaling is launching your Spot Instances according to your specifications

Use `as-describe-auto-scaling-groups`. The command shows details about the group and instances launched. For information about the `as-describe-auto-scaling-groups` command, see Verify Auto Scaling Group Creation in the Auto Scaling Developer Guide.

1. Open a command line and navigate to the bin folder of your Auto Scaling CLI tools directory.
2. Type the command: `/bin/as-describe-auto-scaling-groups spotasg --headers`

Note
The `--headers` option supplies the column name so you know what data is being returned.

The information you get should be similar to the following example.

```bash
AUTO-SCALING-GROUP  GROUP-NAME      LAUNCH-CONFIG  AVAILABILITY-ZONES
MIN-SIZE MAX-SIZE DESIRED-CAPACITY
AUTO-SCALING-GROUP  spotasg         spotlc-5cents  us-east-1b,us-east-1a
1         5         3
INSTANCE INSTANCE-ID  AVAILABILITY-ZONE  STATE      STATUS   LAUNCH-CONFIG
INSTANCE i-2c30d155  us-east-1a         InService  Healthy  spotlc-5cents
INSTANCE i-fe30d187  us-east-1a         InService  Healthy  spotlc-5cents
INSTANCE i-c630d1bf  us-east-1a         InService  Healthy  spotlc-5cents
API Version 2014-02-01
157
```
You can see that Auto Scaling launched three instances in us-east-1a, as you specified, and they
are all running.

3. Additionally, you can find out details about the Spot Instances launched for you by Auto Scaling, by
using the `as-describe-auto-scaling-instances` command.

This is the basic syntax:

```
as-describe-auto-scaling-instances [InstanceId [InstanceId ...]]
[--max-records value] [General Options]
```

Specifying `InstanceId` is optional. If you specify it, the command returns information about the
instance, if it exists. If you don’t specify `InstanceId`, the command returns information about all
instances associated with your Auto Scaling account.

In this walkthrough, we are assuming that you created one launch configuration and Auto Scaling
group, and you want to find out details about all your Spot Instances.

Your command should look like the following example:

```
as-describe-auto-scaling-instances --headers
```

The information you get should be similar to the following example:

```
<table>

What do you want to do next?

- Updating the Bid Price for the Spot Instances (p. 158)
- Scheduling Spot Bid Requests (p. 161)
- Using Auto Scaling to Get Notifications for Spot Instances (p. 161)
- Advanced Tasks (p. 168)

**Updating the Bid Price for the Spot Instances**

Auto Scaling launch configurations cannot be changed. If you want to modify your bid price for Spot
Instances, you must create a new launch configuration.

If you want to launch a set of Spot Instances that have a higher likelihood of running uninterrupted for a
long time, you can use a higher bid price. To do this, you must create a new launch configuration, using
the same procedure that you followed earlier in this walkthrough. (For more information, go to Step 1: Create a Launch Configuration (p. 152).)

Specify the following values:

- Launch configuration name = spotlc-7cents
- Image ID = ami-e565ba8c
Note
If you don't have an AMI, and you want to find a suitable one, see Finding a Suitable AMI (p. 53).

- Instance type = m1.small
- Spot Price = $0.07

Your command should look similar to the following example:

```
as-create-launch-config spotlc-7cents --image-id ami-e565ba8c --instance-type m1.small --spot-price "0.07"
```

You should get a confirmation like the following example:

```
OK-Created launch config
```

After you have created the new launch configuration successfully, create a new Auto Scaling group specifying the new launch configuration.

Your command should look similar to the following example:

```
as-create-auto-scaling-group spotasg-7cents --launch-configuration spotlc-7cents --availability-zones "us-east-1a,us-east-1b" --max-size 5 --min-size 10 --desired-capacity 3
```

You should get a confirmation like the following example:

```
OK-Created AutoScalingGroup
```

You can view the status of your Spot bid and a list of the bids that Auto Scaling placed for you by running `as-describe-scaling-activities` soon after you create your Auto Scaling group.

Your command should look similar to the following example:

```
as-describe-scaling-activities --headers
```

If not all your bids are fulfilled, you will get information that looks like the following example:

```

Bids are represented by values such as sir-93828812 and sir-016cf812.

When you create a new launch configuration that sets a new bid price for Spot Instances, and you have Spot Instances already running based on a different price, these instances will continue running and will only be terminated if the Spot Price goes above the bid price on which it was based.

What do you want to do next?
- Scheduling Spot Bid Requests (p. 161)
Scheduling Spot Bid Requests

You can set up Auto Scaling to launch a certain number of instances at a specific time. This capability is useful if, for example, you want to take advantage of a window of time when prices historically are lower, or you want to terminate Spot Instances at a specific time.

We will use the Auto Scaling CLI command `as-put-scheduled-update-group-action` to set up a schedule. This is the basic syntax:

```
```

In this scenario, use the following values:

- **Scheduled action name:** `as-spotbid-schedule`
- **Auto Scaling group:** `spotasg`
- **Start time:** `2012-05-15T19:10:00Z`
- **End time:** `2012-05-15T19:15:00Z`
- **Desired capacity:** `20`

Your command should look similar to the following example:

```
as-put-scheduled-update-group-action as-spotbid-schedule --auto-scaling-group spotasg --desired-capacity 20 --start-time 2012-05-15T19:10:00Z --end-time 2012-05-15T19:15:00Z
```

You should get a confirmation like the following example:

```
OK-Put Scheduled Update Group Action
```

To check your scheduled action, run `as-describe-scheduled-actions`.

You will get information similar to the following example:

```
UPDATE-GROUP-ACTION spotasg as-spotbid-schedule 2012-05-15T19:10:00Z 20
```

What do you want to do next?

- Obtaining Information About the Instances Launched by Auto Scaling (p. 154)
- Updating the Bid Price for the Spot Instances (p. 158)
- Using Auto Scaling to Get Notifications for Spot Instances (p. 161)
- Advanced Tasks (p. 168)

Using Auto Scaling to Get Notifications for Spot Instances

You can set up Auto Scaling to send notifications to you as instances are terminated and launched. When the Spot Price goes up and your bid price falls below it, Amazon EC2 terminates the instances that were launched based on that bid price. If your Spot Instances are terminated, Auto Scaling will try to submit
your bid and launch replacement instances and to ensure the capacity you specified for your Auto Scaling group. You can set up Auto Scaling to notify you when instance launch or termination events occur.

There are two ways to get notifications for Spot Instances:

- Auto Scaling
- AWS SDK Sample Code Tool

**Spot Notifications Sample in AWS Java SDK**

You can also use the AWS Java SDK to develop applications that monitor your Spot Instance usage in ways that are customized to your use case. The Spot Notifications sample application is a Java application that demonstrates techniques for monitoring Amazon EC2 instance status, Spot Instance requests, and Spot Price fluctuations. The application is documented and freely available for download at How to Track Spot Instance Activity with the Spot-Notifications Sample Application. You are free to adapt the application for your own purposes, or use it as a guide in developing your own application for monitoring Spot Instances. For more information, see the AWS SDK for Java.

**Configuring Auto Scaling groups to send notifications about your Spot Instances**

In this portion of the walkthrough, you learn how to set up Amazon SNS to send email notifications.

To do this, you need the following:

*An Amazon Resource Name (ARN)*. You generate an ARN when you create an Amazon Simple Notification Service (Amazon SNS) topic. A topic is a communication channel to send messages and subscribe to notifications. It provides an access point for publishers and subscribers to communicate with each other. An endpoint, such as an email address, must be subscribed to the topic so the endpoint can receive messages published to the topic. To create a topic, see Create a Topic in the Amazon Simple Notification Service Getting Started Guide.

*An Auto Scaling Group*. Use the Auto Scaling group that you created earlier in this walkthrough.

*A notification configuration*. You configure an Auto Scaling group to send notifications when specified events take place by calling the as-put-notification-configuration CLI command or the PutNotificationConfiguration API action. We will discuss the steps in setting up a notification configuration later in this section. For more information about the command, see PutNotificationConfiguration in the Auto Scaling API Reference.

*A list of Auto Scaling notification types*. These notification types are the events that cause the notification to be sent.

**Set Up Notifications Using Auto Scaling**

1. After you've created your Amazon SNS topic and you have the ARN, you are ready to set up the notification configuration. (To create a topic, see Create a Topic in the Amazon Simple Notification Service Getting Started Guide.)

   To configure your Auto Scaling group to send notifications when specified events take place, use the as-put-notification-configuration CLI command.

   The as-put-notification-configuration command takes the following arguments:

   ```
   as-put-notification-configuration AutoScalingGroupName --notification-types value --topic-arn topic-ARN [General Options]
   ```

   You need to specify the Auto Scaling group name, the ARN, and the notification types.

   For this example, specify:
• Auto Scaling group name: spotasg

Specify the Auto Scaling group that you want to get notifications about. In this walkthrough, you want Auto Scaling to notify you when instances are launched and terminated for the spotasg Auto Scaling group.

• ARN: arn:placeholder:MyTopic

Note
ARNs are unique identifiers for AWS resources. Replace the ARN placeholder with your ARN.

• Notification types: autoscaling:EC2_Instance_Launch, autoscaling:EC2_Instance_Terminate

The notification types are the events you want Auto Scaling to send you e-mail about.

Open a command prompt and enter the as-put-notification-configuration command.

```
```

Auto Scaling returns the following:

```
OK-Put Notification Configuration
```

You now have a notification configuration that sends a notification to the endpoint subscribed in the arn:placeholder:MyTopic ARN whenever instances are launched or terminated.

2. Verify the notification configuration.

To verify the notification actions associated with your Auto Scaling group when specified events take place, use as-describe-notification-configurations.

The as-describe-notification-configurations command takes the following arguments:

```
as-describe-notification-configurations [--auto-scaling-groups value[,value...]] [--maxrecords value] [General Options]
```

If you specify the Auto Scaling group, this command returns a full list of all notification configuration for the Auto Scaling group listed. If you don’t provide an Auto Scaling group name, the service returns the full details of all Auto Scaling groups. The command also returns a token if there are more pages to retrieve. To get the next page, call this action again with the returned token as the next-token argument. For this walkthrough, specify:

• Auto Scaling group name: spotasg

Open a command prompt and enter the as-describe-notification-configurations command.

```
as-describe-notification-configurations --auto-scaling-groups spotasg -headers
```

Auto Scaling returns the following:

```
NOTIFICATION-CONFIG GROUP-NAME TOPIC-ARN NOTIFICATION-TYPE-NAME
NOTIFICATION-CONFIG spotasg arn:placeholder:spotasg autoscaling:EC2_INSTANCE_LAUNCH
NOTIFICATION-CONFIG spotasg arn:placeholder:spotasg autoscaling:EC2_INSTANCE_TERMINATE
```
You have confirmed that you have a notification configuration set up for the spotasg Auto Scaling group.

When Auto Scaling launches instances to reach or maintain desired capacity, as specified in your Auto Scaling group, Amazon SNS sends a notification to your email address with information about the instances. You can check your email Inbox for this information, then run `as-describe-auto-scaling-group` to get information about current instances in the Auto Scaling group and confirm that the instances listed in your email actually exist.

**Using CloudFormation Templates to Launch Spot Instances**

You can use AWS CloudFormation templates to launch Spot Instances and the AWS resources you need for an application. Templates are text files describing a collection, called a stack, of AWS resources that you want to deploy as a group. For more information about AWS CloudFormation templates, see Learn Template Basics. For more information about using AWS CloudFormation, see the AWS CloudFormation User Guide.

You can write your own template from scratch, or you can use one of the example templates from the AWS CloudFormation Sample Template Library. The following templates in AWS CloudFormation utilize Spot Instances:

- **Asynchronous Queue-Based Processing**

  This template creates an auto-scaled worker that monitors work (messages) in a queue. The application is auto-scaled based on the amount of work in the queue. When there is work, Auto Scaling scales up; when there is no work, Auto Scaling scales down. Each message contains a command/script to run, an input file location, and an output location for the results.

  To download this template, go to Asynchronous Queue-Based Processing.

- **Bees with Machine Guns**

  This template creates a load balancer, a controller, and the instances behind the load balancer: fires up and triggers an attack; stores logs on Amazon Simple Storage Service (Amazon S3) and then shuts down (if enabled). For this template, instances use the Amazon Linux AMI, and the setup requires that you already have an AWS Identity and Access Management (IAM) SSL certification. You can modify this template to remove the SSL dependencies.

  **Note**

  To launch this template, you need a new SSH private key that you create specifically for this task. You'll have to log in to the instance created by the template and provide this private key information.

  To download this template, go to Bees with Machine Guns.

- **Grid Computing for Spot Instances**

  This template uses Star Cluster to launch and bootstrap a cluster of Amazon EC2 instances for high performance computational tasks using Spot pricing. You only need to provide the number of instances, instance size, and Spot Price that you want to use.

  To download this template, go to Grid Computing for Spot Instances.
You can create stacks from these templates by using the AWS Management Console, the AWS CloudFormation command line interface tools, or the AWS CloudFormation API.

Before you use these templates, you must:

1. Have an AWS account and sign up for AWS CloudFormation.
2. Decide on the template to use.
3. Enter the parameters required for the stack.
4. Create the stack.

To get started with AWS CloudFormation, see Getting Started with AWS CloudFormation in the AWS CloudFormation User Guide.

**Launching Amazon Elastic MapReduce Job Flows with Spot Instances**

You can launch an Amazon Elastic MapReduce job flow in Spot Instances. Amazon EMR is a data analysis tool that simplifies the set up and management of a computer cluster, the source data, and the computational tools that help you implement sophisticated data processing jobs quickly. For more information, see What is Amazon EMR?.

In addition, you can use Spot Instances with Amazon EMR clusters and AWS Data Pipeline. For information, see Amazon EC2 Spot Instances with Amazon EMR Clusters and AWS Data Pipeline.

**Quick Look: Using Spot Instances with Amazon Elastic MapReduce Video**

The following video describes how Spot Instances work in Amazon EMR and walks you through the process of launching a job flow on Spot Instances from the AWS Management Console: Using Spot Instances with Amazon ElasticMapReduce.

**Launching Spot Instances in Amazon Virtual Private Cloud**

Amazon Virtual Private Cloud (Amazon VPC) lets you define a virtual networking environment in a private, isolated section of the Amazon Web Services (AWS) cloud. You have complete control of this virtual network and you can use advanced security features and network access control at the instance level and subnet level. For more information about Amazon VPC, see the Amazon Virtual Private Cloud User Guide.

If you want to take advantage of the features of Amazon VPC when you use Spot Instances, specify in your Spot request that your instances are to be launched in a VPC. To ensure that your Spot Instances are launched in a VPC:

- Determine if your AWS account supports a default VPC. For more information, see Detecting Your Supported Platforms and Whether You Have a Default VPC.
- If your AWS account supports a default VPC, determine whether you want to launch your instances in that VPC. You don't have to perform any additional steps when you request Spot Instances. The Request Spot Instances wizard lists the VPC ID in the Network field.
- If your AWS account supports a default VPC, determine whether you want to use a different VPC for your Spot Instances. You can create a new VPC and specify the ID of the VPC that you just created.
- If your AWS account does not support a default VPC, create a VPC and specify the ID of the VPC that you just created.
For more information about default VPCs, see Default VPC Basics. For more information about setting up a VPC, see Getting Started with Amazon VPC in the Amazon Virtual Private Cloud Getting Started Guide.

Quick Look: Launching Spot Instances in Amazon VPC Video

The following video shows how to launch your first Spot Instance in Amazon VPC using the AWS Management Console. This video includes instructions for creating your VPC subnet, placing a bid, determining when the instance is fulfilled, and canceling the instance. Launching Spot Instances in Amazon VPC Video

Understanding the Process for Launching Spot Instances in Amazon VPC

The process for making a Spot Instance request that launches in a VPC is the same as the process you follow when you make a Spot Instance request in a non-VPC portion of Amazon EC2—except for the following differences:

You should base your bid on the Spot Price history of Spot Instances in VPCs.

When you use the describe-spot-price-history AWS CLI command or the ec2-describe-spot-price-history Amazon EC2 CLI command, add (Amazon VPC) to the product-description filter.

Using the AWS CLI, here's how the command looks:

```
$ aws ec2 describe-spot-price-history --instance-types m1.xlarge --product-description "Linux/UNIX (Amazon VPC)" --start-time 2014-01-06T07:08:09 --end-time 2014-01-06T08:09:10
```

Using the AWS Management Console, check the Spot Instance Pricing History page to see the Spot pricing history for Amazon EC2 instances running in both Amazon EC2 and Amazon VPC.

You have to specify the VPC in which you want to launch your Spot Instance.
When you use the `aws ec2 request-spot-instances` AWS CLI command or the `ec2-request-spot-instances` Amazon EC2 CLI command, specify the ID of the VPC subnet in which you want to launch the Spot Instance.

Using AWS CLI, here’s how the command looks:

```bash
$ aws ec2 request-spot-instances --spot-price "0.050" --instance-count 5 --type "one-time" --launch-specification "{"ImageId":"ami-a43909e1","Instance Type":"m1.small","SubnetId":"subnet-d50bfebc"}"
```

Using the AWS Management Console, when you launch the Request Spot Instances wizard from the Spot Requests page of the Amazon EC2 console, in the Configure Instance Details page, select a VPC from the Network drop-down. What the Network displays depends on whether or not your account supports a default VPC. (For more information, see Detecting Your Supported Platforms and Whether You Have a Default VPC.)

- If your account is EC2-Classic and therefore does not support a default VPC, Network will show VPC options if you have a VPC before making the Spot Request. For example, if you are requesting Spot Instances in us-east-1 and you have VPCs, Network will list the VPC subnets available for the region’s Availability Zones.

  ![Network Options](image)

  If you don’t have a VPC, click Create new VPC. The VPC Management Console opens in a new tab. Click Create VPC and follow the wizard to create a new VPC.

  ![Create VPC](image)

- If your account supports a default VPC, Network will list the default VPC. You will also see a Subnet drop-down list that shows the default subnets for the Availability Zones in the region in which you’re requesting your Spot Instances. You can opt to create a new VPC or a new subnet.

  ![Default Subnet](image)

If you want your Spot Instance launched in a specific low-priced Availability Zone, you must specify the subnet in your Spot Instance request.

The subnet you choose also determines the Availability Zone in which your Spot Instance will be launched. If you do not specify a subnet and Availability Zone when you submit your Spot Instance request, your Spot Instance will be placed in the subnet of an available Availability Zone. The Availability Zone might not have the lowest Spot price.
If your account supports a default VPC and you do not specify a subnet and Availability Zone in your Spot request, the default VPC that the placement system chooses might be different from the Availability Zone with the lowest Spot price.

For more information about using Amazon VPC, see the Amazon Virtual Private Cloud User Guide.

Advanced Tasks

Now that you have created Spot Instance requests and worked with Spot Instances, this section discusses some advanced tasks.

- Subscribe to Your Spot Instance Data Feed (p. 168)
- Programming Spot Instances the with AWS Java SDK (p. 171)
- Starting Clusters on Spot Instances (p. 196)

If you think we should add other advanced tasks to this section, let us know at spot-instance-feedback@amazon.com.

Subscribe to Your Spot Instance Data Feed

If you want to monitor your Spot Instance usage, you can subscribe to your Spot Instance data feed, which stores usage logs in Amazon Simple Storage Service (Amazon S3).

This section describes the data feed content and how to create the data feed for Spot Instances. You can create one data feed per account.

Spot Instance Data Feed Overview

To help you understand the charges for your Spot Instances, Amazon EC2 provides access to a data feed that details your Spot Instance usage and pricing. This data feed is sent to the Amazon S3 bucket of your choice.

To have a data feed delivered to an Amazon S3 bucket, you need to create a Spot Instances data feed subscription using the Amazon EC2 API. When you create this subscription, you can specify an Amazon S3 bucket to deliver the data feed files to, and a filename prefix to use to avoid collisions.

Data Feed Filename and Format

The Spot Instance data feed filename uses the following format (with the date and hour in UTC):

{Bucket}.s3.amazonaws.com/{Optional Prefix}/{AWS Account ID}.{YYYY}-{MM}-{DD}-{HH}.{n}.{Unique ID}.gz

For example, if your bucket name is myawsbucket, and you name your prefix myprefix, your filenames look similar to this:

myawsbucket.s3.amazonaws.com/myprefix/111122223333.2010-03-17-20.001.pwBdGTJG.gz

Data feed files arrive in your bucket typically once an hour and each hour of usage is typically covered in a single data file. These files are compressed (gzip) before delivery into your bucket. We can write multiple files for a given hour of usage where files are very large (for example, when file contents for the hour exceed 50 MB before compression).
Note
If you don't have a Spot Instance running during a certain hour, you won't receive a data feed file for that hour.

The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance-hour. Each line contains the fields listed in the following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timestamp</td>
<td>The timestamp used to determine the price charged for this instance-hour.</td>
</tr>
<tr>
<td>UsageType</td>
<td>Indicates the type of usage and instance type being charged for. For m1.small Spot Instances, this field is set to &quot;SpotUsage.&quot; For all other instance types, this field is set to &quot;SpotUsage:{instance-type},&quot; for example, &quot;SpotUsage:c1.medium.&quot;</td>
</tr>
<tr>
<td>Operation</td>

Preparing Amazon S3 for Data Feeds

When you subscribe to data feeds, you tell Amazon EC2 which bucket you want to store the data feed file in. Before you subscribe to the data feed, consider the following when choosing your Amazon S3 bucket:

- You must have Amazon S3 FULL_CONTROL permission on the bucket you provide.
  - If you're the bucket owner, you have this permission by default. If you're not the bucket owner, the bucket owner must grant your AWS account FULL_CONTROL permission.
- When you create your data feed subscription, Amazon EC2 updates the designated bucket's ACL to allow read and write permissions for the AWS data feeds account.
- Each data feed file has its own ACL (separate from the bucket's ACL).

The bucket owner has FULL_CONTROL permission for the data files. The data feed account has read and write permission.

- Removing the permissions for the data feed account does not disable the data feed.
  - If you remove those permissions but don't disable the data feed (which you do with the control API), we reinstate those permissions the next time the data feeds account needs to write a data file to your bucket.
- If you delete your data feed subscription, Amazon EC2 doesn't remove the read/write permissions for the data feed account on either the bucket or the data files.

You must perform remove the read/write permissions yourself.
Subscribe to Your Spot Instance Data Feed

Amazon EC2 Command Line Interface (CLI) Tools

To subscribe to your Spot Instance data feed

• Enter the following command:

```
$ ec2-create-spot-datafeed-subscription --bucket myawsbucket [--prefix prefix ]
```

Amazon EC2 returns output similar to the following:

```
SPOTDATAFEEDSUBSCRIPTION        111122223333    myawsbucket        prefix
Active
```

API

To subscribe to your Spot Instance data feed

• Construct the following Query request.

```
https://ec2.amazonaws.com/
?Action=CreateSpotDatafeedSubscription
&Bucket=myawsbucket
&Prefix=my-spot-subscription
&...auth parameters...
```

Following is an example response.

```
<CreateSpotDatafeedSubscriptionResponse xmlns="http://ec2.amazonaws.com/doc/2014-02-01/">
  <requestId>59dbff89-35bd-4ec9-99ed-be587EXAMPLE</requestId>
  <spotDatafeedSubscription>
    <ownerId>999988887777</ownerId>
    <bucket>myawsbucket</bucket>
    <prefix>my-spot-subscription</prefix>
    <state>Active</state>
    <fault/>
  </spotDatafeedSubscription>
</CreateSpotDatafeedSubscriptionResponse>
```

Delete a Spot Instance Data Feed

Command Line Tools

To delete a Spot Instance data feed

• To delete a data feed, enter the following command:
ec2-delete-spot-datafeed-subscription

If the request is successful, the output is empty.

API

To delete a Spot Instance data feed

• Construct the following Query request.

```plaintext
https://ec2.amazonaws.com/
?Action=DeleteSpotDatafeedSubscription
&...auth parameters...
```

Following is an example response. It confirms that the subscription was deleted.

```xml
<DeleteSpotDatafeedSubscriptionResponse xmlns="http://ec2.amazonaws.com/doc/2014-02-01/">

Programming Spot Instances the with AWS Java SDK

You can use the AWS Java SDK to program Spot Instances:

• Tutorial: Amazon EC2 Spot Instances (p. 172)
• Tutorial: Advanced Amazon EC2 Spot Request Management (p. 180)
Tutorial: Amazon EC2 Spot Instances

Overview

Spot Instances allow you to bid on unused Amazon Elastic Compute Cloud (Amazon EC2) capacity and run the acquired instances for as long as your bid exceeds the current Spot Price. Amazon EC2 changes the Spot Price periodically based on supply and demand, and customers whose bids meet or exceed it gain access to the available Spot Instances. Like On-Demand Instances and Reserved Instances, Spot Instances provide you another option for obtaining more compute capacity.

Spot Instances can significantly lower your Amazon EC2 costs for batch processing, scientific research, image processing, video encoding, data and web crawling, financial analysis, and testing. Additionally, Spot Instances give you access to large amounts of additional capacity in situations where the need for that capacity is not urgent.

To use Spot Instances, place a Spot Instance request specifying the maximum price you are willing to pay per instance hour; this is your bid. If your bid exceeds the current Spot Price, your request is fulfilled and your instances will run until either you choose to terminate them or the Spot Price increases above your bid (whichever is sooner).

It’s important to note two points:

• You will often pay less per hour than your bid. Amazon EC2 adjusts the Spot Price periodically as requests come in and available supply changes. Everyone pays the same Spot Price for that period regardless of whether their bid was higher. Therefore, you might pay less than your bid, but you will never pay more than your bid.

• If you’re running Spot Instances and your bid no longer meets or exceeds the current Spot Price, your instances will be terminated. This means that you will want to make sure that your workloads and applications are flexible enough to take advantage of this opportunistic capacity.

Spot Instances perform exactly like other Amazon EC2 instances while running, and like other Amazon EC2 instances, Spot Instances can be terminated when you no longer need them. If you terminate your instance, you pay for any partial hour used (as you would for On-Demand or Reserved Instances). However, if the Spot Price goes above your bid and your instance is terminated by Amazon EC2, you will not be charged for any partial hour of usage.

This tutorial provides a quick overview of how to use the Java programming language to do the following.

• Submit a Spot Request
• Determine when the Spot Request becomes fulfilled
• Cancel the Spot Request
• Terminate associated instances

Prerequisites

To use this tutorial you need to be signed up for Amazon Web Services (AWS). If you have not yet signed up for AWS, go to the Amazon Web Services website, and click Create an AWS Account in the upper right corner of the page. In addition, you also need to install the AWS Java SDK.

If you are using the Eclipse development environment, we recommend that you install the AWS Toolkit for Eclipse. Note that the AWS Toolkit for Eclipse includes the latest version of the AWS SDK for Java.

Step 1: Setting Up Your Credentials

To begin using this code sample, you need to populate your credentials in the AwsCredentials.properties file. Specifically, you need to populate your secret key and access key.
Copy and paste your Access Key and Secret Access Key into the AwsCredentials.properties file.

Now that you have configured your settings, you can get started using the code in the example.

**Step 2: Setting Up a Security Group**

A security group acts as a firewall that controls the traffic allowed in and out of a group of instances. By default, an instance is started without any security group, which means that all incoming IP traffic, on any TCP port will be denied. So, before submitting our Spot Request, we will set up a security group that allows the necessary network traffic. For the purposes of this tutorial, we will create a new security group called "GettingStarted" that allows Secure Shell (SSH) traffic from the IP address where you are running your application from. To set up a new security group, you need to include or run the following code sample that sets up the security group programmatically.

After we create an AmazonEC2 client object, we create a CreateSecurityGroupRequest object with the name, "GettingStarted" and a description for the security group. Then we call the ec2.createSecurityGroup API to create the group.

To enable access to the group, we create an ipPermission object with the IP address range set to the CIDR representation of the subnet for the local computer; the "/10" suffix on the IP address indicates the subnet for the specified IP address. We also configure the ipPermission object with the TCP protocol and port 22 (SSH). The final step is to call ec2.authorizeSecurityGroupIngress with the name of our security group and the ipPermission object.

```java
// Retrieves the credentials from an AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
        GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

// Create a new security group.
try {
    CreateSecurityGroupRequest securityGroupRequest = new CreateSecurityGroupRequest(
            "GettingStartedGroup", "Getting Started Security Group");
    ec2.createSecurityGroup(securityGroupRequest);
} catch (AmazonServiceException ase) {
    // Likely this means that the group is already created, so ignore.
    System.out.println(ase.getMessage());
}

String ipAddr = "0.0.0.0/0";

// Get the IP of the current host, so that we can limit the Security
// Group by default to the ip range associated with your subnet.
try {
    InetAddress addr = InetAddress.getLocalHost();
    
```
// Get IP Address
ipAddr = addr.getHostAddress()+"/10";
} catch (UnknownHostException e) {
    
    // Create a range that you would like to populate.
    ArrayList<String> ipRanges = new ArrayList<String>();
    ipRanges.add(ipAddr);

    // Open up port 22 for TCP traffic to the associated IP
    // from above (e.g. ssh traffic).
    ArrayList<IpPermission> ipPermissions = new ArrayList<IpPermission> ();
    IpPermission ipPermission = new IpPermission();
    ipPermission.setIpProtocol("tcp");
    ipPermission.setFromPort(new Integer(22));
    ipPermission.setToPort(new Integer(22));
    ipPermission.setIpRanges(ipRanges);
    ipPermissions.add(ipPermission);

    try {
        // Authorize the ports to the used.
        AuthorizeSecurityGroupIngressRequest ingressRequest =
            new AuthorizeSecurityGroupIngressRequest("GettingStartedGroup",ip
Permissions);
        ec2.authorizeSecurityGroupIngress(ingressRequest);
    } catch (AmazonServiceException ase) {
        // Ignore because this likely means the zone has
        // already been authorized.
        System.out.println(ase.getMessage());
    }

You can view this entire code sample in the CreateSecurityGroupApp.java code sample. Note you
only need to run this application once to create a new security group.

You can also create the security group using the AWS Toolkit for Eclipse. Go to the toolkit documentation
for more information.

**Step 3: Submitting Your Spot Request**

To submit a Spot request, you first need to determine the instance type, Amazon Machine Image (AMI),
and maximum bid price you want to use. You must also include the security group we configured previously,
so that you can log into the instance if desired.

There are several instance types to choose from; see Instance Types (p. 97) for a complete list. For this
tutorial, we will use t1.micro, the cheapest instance type available. Next, we will determine the type of
AMI we would like to use. We'll use ami-8c1fece5, the most up-to-date Amazon Linux AMI available when
we wrote this tutorial. The latest AMI may change over time, but you can always determine the latest
version AMI by:

1. Logging into the AWS Management Console, clicking the EC2 tab, and, from the EC2 Console
   Dashboard, attempting to launch an instance.
2. In the window that displays AMIs, just use the AMI ID as shown in the wizard. Alternatively, you can use the DescribeImages API, but leveraging that command is outside the scope of this tutorial.

There are many ways to approach bidding for Spot instances; to get a broad overview of the various approaches you should view the Bidding for Spot Instances video. However, to get started, we'll describe three common strategies: bid to ensure cost is less than on-demand pricing; bid based on the value of the resulting computation; bid so as to acquire computing capacity as quickly as possible.

- **Reduce Cost below On-Demand** You have a batch processing job that will take a number of hours or days to run. However, you are flexible with respect to when it starts and when it completes. You want to see if you can complete it for less cost than with On-Demand Instances. You examine the Spot Price history for instance types using either the AWS Management Console or the Amazon EC2 API. For more information, see Viewing Spot Instance Pricing History (p. 125). After you've analyzed the price history for your desired instance type in a given Availability Zone, you have two alternative approaches for your bid:
  - You could bid at the upper end of the range of Spot Prices (which are still below the On-Demand price), anticipating that your one-time Spot request would most likely be fulfilled and run for enough consecutive compute time to complete the job.
  - Or, you could bid at the lower end of the price range, and plan to combine many instances launched over time through a persistent request. The instances would run long enough—in aggregate—to complete the job at an even lower total cost. (We will explain how to automate this task later in this tutorial.)

- **Pay No More than the Value of the Result** You have a data processing job to run. You understand the value of the job's results well enough to know how much they are worth in terms of computing costs. After you've analyzed the Spot Price history for your instance type, you choose a bid price at which the cost of the computing time is no more than the value of the job's results. You create a persistent bid and allow it to run intermittently as the Spot Price fluctuates at or below your bid.

- **Acquire Computing Capacity Quickly** You have an unanticipated, short-term need for additional capacity that is not available through On-Demand Instances. After you've analyzed the Spot Price history for your instance type, you bid above the highest historical price to provide a high likelihood that your request will be fulfilled quickly and continue computing until it completes.

After you choose your bid price, you are ready to request a Spot Instance. For the purposes of this tutorial, we will bid the On-Demand price ($0.03) to maximize the chances that the bid will be fulfilled. You can determine the types of available instances and the On-Demand prices for instances by going to Amazon EC2 Pricing page. To request a Spot Instance, you simply need to build your request with the parameters you chose earlier. We start by creating a RequestSpotInstanceRequest object. The request object requires the number of instances you want to start and the bid price. Additionally, you need to set the LaunchSpecification for the request, which includes the instance type, AMI ID, and security group you want to use. Once the request is populated, you call the requestSpotInstances method on the AmazonEC2Client object. The following example shows how to request a Spot Instance.
// Retrieves the credentials from a AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
        GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

// Initializes a Spot Instance Request
RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

// Request 1 x t1.micro instance with a bid price of $0.03.
requestRequest.setSpotPrice("0.03");
requestRequest.setInstanceCount(Integer.valueOf(1));

// Setup the specifications of the launch. This includes the
// instance type (e.g. t1.micro) and the latest Amazon Linux
// AMI id available. Note, you should always use the latest
// Amazon Linux AMI id or another of your choosing.
LaunchSpecification launchSpecification = new LaunchSpecification();
launchSpecification.setImageId("ami-8c1fece5");
launchSpecification.setInstanceType("t1.micro");

// Add the security group to the request.
ArrayList<String> securityGroups = new ArrayList<String>();
securityGroups.add("GettingStartedGroup");
launchSpecification.setSecurityGroups(securityGroups);

// Add the launch specifications to the request.
requestRequest.setLaunchSpecification(launchSpecification);

// Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);

Running this code will launch a new Spot Instance Request. There are other options you can use to
configure your Spot Requests. To learn more, see Tutorial: Advanced Amazon EC2 Spot Request
Management (p. 180) or the RequestSpotInstances API in the Java SDK.

**Note**
You will be charged for any Spot Instances that are actually launched, so make sure that you
cancel any requests and terminate any instances you launch to reduce any associated fees.
Step 4: Determining the State of Your Spot Request

Next, we want to create code to wait until the Spot request reaches the "active" state before proceeding to the last step. To determine the state of our Spot request, we poll the describeSpotInstanceRequests method for the state of the Spot request ID we want to monitor.

The request ID created in Step 2 is embedded in the response to our requestSpotInstances request. The following example code shows how to gather request IDs from the requestSpotInstances response and use them to populate an ArrayList.

```java
1 // Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);
List<SpotInstanceRequest> requestResponses = requestResult.getSpotInstanceRequests();
5 // Setup an arraylist to collect all of the request ids we want to
// watch hit the running state.
ArrayList<String> spotInstanceRequestIds = new ArrayList<String>();
10 // Add all of the request ids to the hashset, so we can determine when they
// hit the
// active state.
for (SpotInstanceRequest requestResponse : requestResponses) {
    System.out.println("Created Spot Request: "+requestResponse.getSpotInstanceRequestId());
    spotInstanceRequestIds.add(requestResponse.getSpotInstanceRequestId());
15 }
```

To monitor your request ID, call the describeSpotInstanceRequests method to determine the state of the request. Then loop until the request is not in the "open" state. Note that we monitor for a state of not "open", rather a state of, say, "active", because the request can go straight to "closed" if there is a problem with your request arguments. The following code example provides the details of how to accomplish this task.

```java
1 // Create a variable that will track whether there are any
// requests still in the open state.
boolean anyOpen;
5 do {
    // Create the describeRequest object with all of the request ids
    // to monitor (e.g. that we started).
    DescribeSpotInstanceRequestsRequest describeRequest = new DescribeSpotInstanceRequestsRequest();
10    describeRequest.setSpotInstanceRequestIds(spotInstanceRequestIds);

    // Initialize the anyOpen variable to false - which assumes there
    // are no requests open unless we find one that is still open.
    anyOpen=false;
15    try {
        // Retrieve all of the requests we want to monitor.
        DescribeSpotInstanceRequestsResult describeResult = ec2.describeSpotInstanceRequests(describeRequest);
```
List<SpotInstanceRequest> describeResponses = describeResult.getSpotInstanceRequests();

// Look through each request and determine if they are all in
// the active state.
for (SpotInstanceRequest describeResponse : describeResponses) {
    // If the state is open, it hasn't changed since we attempted
    // to request it. There is the potential for it to transition
    // almost immediately to closed or canceled so we compare
    // against open instead of active.
    if (describeResponse.getState().equals("open")) {
        anyOpen = true;
        break;
    }
}
}
catch (AmazonServiceException e) {
    // If we have an exception, ensure we don't break out of
    // the loop. This prevents the scenario where there was
    // blip on the wire.
    anyOpen = true;
}

try {
    // Sleep for 60 seconds.
    Thread.sleep(60*1000);
} catch (Exception e) {
    // Do nothing because it woke up early.
}
} while (anyOpen);

After running this code, your Spot Instance Request will have completed or will have failed with an error
that will be output to the screen. In either case, we can proceed to the next step to clean up any active
requests and terminate any running instances.

Step 5: Cleaning Up Your Spot Requests and Instances

Lastly, we need to clean up our requests and instances. It is important to both cancel any outstanding
requests and terminate any instances. Just canceling your requests will not terminate your instances,
which means that you will continue to pay for them. If you terminate your instances, your Spot requests
may be canceled, but there are some scenarios—such as if you use persistent bids—where terminating
your instances is not sufficient to stop your request from being re-fulfilled. Therefore, it is a best practice
to both cancel any active bids and terminate any running instances.

The following code demonstrates how to cancel your requests.

try {
    // Cancel requests.
    CancelSpotInstanceRequestsRequest cancelRequest = new CancelSpotInstancesRequest(spotInstanceRequestIds);
    ec2.cancelSpotInstanceRequests(cancelRequest);
} catch (AmazonServiceException e) {
    // Write out any exceptions that may have occurred.
    System.out.println("Error canceling instances");
    System.out.println("Caught Exception: "+e.getMessage());
    System.out.println("Response Status Code: "+e.getStatusCode());
}
To terminate any outstanding instances, you will need the instance ID associated with the request that started them. The following code example takes our original code for monitoring the instances and adds an `ArrayList` in which we store the instance ID associated with the `describeInstance` response.

```java
// Create a variable that will track whether there are any requests still in the open state.
boolean anyOpen;

// Initialize variables.
ArrayList<String> instanceIds = new ArrayList<String>();
do {
    // Create the describeRequest with all of the request ids to monitor (e.g. that we started).
    DescribeSpotInstanceRequestsRequest describeRequest = new DescribeSpotInstanceRequestsRequest();
    describeRequest.setSpotInstanceRequestIds(spotInstanceRequestIds);
    describeRequest.setSpotInstanceRequestIds(spotInstanceRequestIds);

    // Initialize the anyOpen variable to false, which assumes there are no requests open unless we find one that is still open.
    anyOpen = false;
    try {
        // Retrieve all of the requests we want to monitor.
        DescribeSpotInstanceRequestsResult describeResult = ec2.describeSpotInstanceRequests(describeRequest);
        List<SpotInstanceRequest> describeResponses = describeResult.getSpotInstanceRequests();

        // Look through each request and determine if they are all in the active state.
        for (SpotInstanceRequest describeResponse : describeResponses) {
            // If the state is open, it hasn't changed since we attempted to request it. There is the potential for it to transition almost immediately to closed or canceled so we compare against open instead of active.
            if (describeResponse.getState().equals("open")) {
                anyOpen = true;
                break;
            }
        }

        // Add the instance id to the list we will eventually terminate.
        instanceIds.add(describeResponse.getInstanceId());
    } catch (AmazonServiceException e) {
        // If we have an exception, ensure we don't break out of the loop. This prevents the scenario where there was a blip on the wire.
        anyOpen = true;
    }
} while (anyOpen);
```
try {
    // Sleep for 60 seconds.
    Thread.sleep(60*1000);
50     } catch (Exception e) {
    // Do nothing because it woke up early.
    }
} while (anyOpen);

Using the instance IDs, stored in the ArrayList, terminate any running instances using the following code snippet.

1 try {
    // Terminate instances.
    TerminateInstancesRequest terminateRequest = new TerminateInstancesRequest(instanceIds);
    ec2.terminateInstances(terminateRequest);
} catch (AmazonServiceException e) {
    // Write out any exceptions that may have occurred.
    System.out.println("Error terminating instances");
    System.out.println("Caught Exception: " + e.getMessage());
    System.out.println("Response Status Code: " + e.getStatusCode());
    System.out.println("Error Code: " + e.getErrorCode());
    System.out.println("Request ID: " + e.getRequestId());
    }

Bringing It All Together

To bring this all together, we provide a more object-oriented approach that combines the preceding steps we showed: initializing the EC2 Client, submitting the Spot Request, determining when the Spot Requests are no longer in the open state, and cleaning up any lingering Spot request and associated instances. We create a class called Requests that performs these actions.

We also create a GettingStartedApp class, which has a main method where we perform the high level function calls. Specifically, we initialize the Requests object described previously. We submit the Spot Instance request. Then we wait for the Spot request to reach the “Active” state. Finally, we clean up the requests and instances.

The complete source code is available for download at GitHub.

Congratulations! You have just completed the getting started tutorial for developing Spot Instance software with the AWS Java SDK.

Next Steps

We recommend that you take the Java Developers: Tutorial: Advanced Amazon EC2 Spot Request Management (p. 180).

Tutorial: Advanced Amazon EC2 Spot Request Management

Overview

Spot Instances allow you to bid on unused Amazon Elastic Compute Cloud (Amazon EC2) capacity and run those instances for as long as your bid exceeds the current Spot Price. Amazon EC2 changes the
Spot Price periodically based on supply and demand. Customers whose bids meet or exceed the Spot Price gain access to the available Spot Instances. Like On-Demand Instances and Reserved Instances, Spot Instances provide you an additional option for obtaining more compute capacity.

Spot Instances can significantly lower your Amazon EC2 costs for batch processing, scientific research, image processing, video encoding, data and web crawling, financial analysis, and testing. Additionally, Spot Instances can provide access to large amounts of additional compute capacity when your need for the capacity is not urgent.

This tutorial provides a quick overview of some advanced Spot Request features, such as detailed options to create Spot requests, alternative methods for launching Spot Instances, and methods to manage your instances. This tutorial is not meant to be a complete list of all advanced topics associated with Spot Instances. Instead, it gives you a quick reference of code samples for some of the commonly used methods for managing Spot Requests and Spot Instances.

Prerequisites

To use this tutorial, you need to be signed up for Amazon Web Services (AWS). If you have not yet signed up for AWS, go to the Amazon Web Services website, and click Sign Up in the upper right corner of the page. In addition, you also need to install the AWS SDK for Java.

If you are using the Eclipse development environment, we recommend that you install the AWS Toolkit for Eclipse. Note that the Toolkit for Eclipse includes the latest version of the AWS SDK for Java.

Step 1: Setting Up Your Credentials

To begin using this code sample, you need to populate your credentials in the AwsCredentials.properties file. Specifically, you need to populate your secretKey and accessKey.

Copy and paste your access key ID and secret access key into the AwsCredentials.properties file.

Step 2: Setting Up a Security Group

Additionally, you need to configure your security group. A security group acts as a firewall that controls the traffic allowed in and out of a group of instances. By default, an instance is started without any security group, which means that all incoming IP traffic, on any TCP port will be denied. So, before submitting our Spot Request, we will set up a security group that allows the necessary network traffic. For the purposes of this tutorial, we will create a new security group called "GettingStarted" that allows Secure Shell (SSH) traffic from the IP address where you are running your application from. To set up a new security group, you need to include or run the following code sample that sets up the security group programmatically.

After we create an AmazonEC2 client object, we create a CreateSecurityGroupRequest object with the name, "GettingStarted" and a description for the security group. Then we call the ec2.createSecurityGroup API to create the group.

To enable access to the group, we create an ipPermission object with the IP address range set to the CIDR representation of the subnet for the local computer; the "/10" suffix on the IP address indicates the subnet for the specified IP address. We also configure the ipPermission object with the TCP protocol and port 22 (SSH). The final step is to call ec2.authorizeSecurityGroupIngress with the name of our security group and the ipPermission object.

(The following code is the same as what we used in the first tutorial.)

```java
1   // Retrieves the credentials from an AWSCredentials.properties file. 
  AWSCredentials credentials = null;
  try {
      credentials = new PropertiesCredentials(
          GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties").getInputStream());
  }
```
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(creds);

// Create a new security group.
try {
    CreateSecurityGroupRequest securityGroupRequest =
        new CreateSecurityGroupRequest("GettingStartedGroup", "Getting Started Security Group");
    ec2.createSecurityGroup(securityGroupRequest);
} catch (AmazonServiceException ase) {
    // Likely this means that the group is already created, so ignore.
    System.out.println(ase.getMessage());
}

String ipAddr = "0.0.0.0/0";

// Get the IP of the current host, so that we can limit the security group
// by default to the IP range associated with your subnet.
try {
    InetAddress addr = InetAddress.getLocalHost();
    // Get IP Address
    ipAddr = addr.getHostAddress()+"/10";
} catch (UnknownHostException e) {
}

// Create a range that you would like to populate.
ArrayList<String> ipRanges = new ArrayList<String>();
ipRanges.add(ipAddr);

// Open up port 22 for TCP traffic to the associated IP from
// above (e.g., ssh traffic).
ArrayList<IpPermission> ipPermissions = new ArrayList<IpPermission>();
IpPermission ipPermission = new IpPermission();
ipPermission.setIpProtocol("tcp");
ipPermission.setFromPort(new Integer(22));
ipPermission.setToPort(new Integer(22));
ipPermission.setIpRanges(ipRanges);
ipPermissions.add(ipPermission);

try {
    // Authorize the ports to the used.
    AuthorizeSecurityGroupIngressRequest ingressRequest =
        new AuthorizeSecurityGroupIngressRequest("GettingStartedGroup", ipPermissions);
    ec2.authorizeSecurityGroupIngress(ingressRequest);
} catch (AmazonServiceException ase) {
    // Ignore because this likely means the zone has already
    // been authorized.
    System.out.println(ase.getMessage());
}
You can view this entire code sample in the `advanced.CreateSecurityGroupApp.java` code sample. Note you only need to run this application once to create a new security group.

You can also create the security group using the AWS Toolkit for Eclipse. Go to the toolkit documentation for more information.

**Detailed Spot Instance Request Creation Options**

As we explained in Tutorial: Amazon EC2 Spot Instances (p. 172), you need to build your request with an instance type, an Amazon Machine Image (AMI), and maximum bid price.

Let's start by creating a `RequestSpotInstanceRequest` object. The request object requires the number of instances you want and the bid price. Additionally, we need to set the `LaunchSpecification` for the request, which includes the instance type, AMI ID, and security group you want to use. After the request is populated, we call the `requestSpotInstances` method on the `AmazonEC2Client` object. An example of how to request a Spot Instance follows.

(The following code is the same as what we used in the first tutorial.)

```java
1 // Retrieves the credentials from an AWSCredentials.properties file.
2 AWSCredentials credentials = null;
3 try {
4     credentials = new PropertiesCredentials(
5         GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
6     } catch (IOException e1) {
7         System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
8         System.out.println(e1.getMessage());
9         System.exit(-1);
10     }

15 // Create the AmazonEC2Client object so we can call various APIs.
16 AmazonEC2 ec2 = new AmazonEC2Client(credentials);

20 // Initializes a Spot Instance request
21 RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

25 // Request 1 x t1.micro instance with a bid price of $0.03.
26 requestRequest.setSpotPrice("0.03");
27 requestRequest.setInstanceCount(Integer.valueOf(1));

30 // Set up the specifications of the launch. This includes the
31 instance type (e.g., t1.micro) and the latest Amazon Linux
32 AMI id available. Note, you should always use the latest
33 Amazon Linux AMI id or another of your choosing.
34 LaunchSpecification launchSpecification = new LaunchSpecification();
35 launchSpecification.setImageId("ami-8c1fece5");
36 launchSpecification.setInstanceType("t1.micro");

40 // Add the security group to the request.
41 ArrayList<String> securityGroups = new ArrayList<String>();
42 securityGroups.add("GettingStartedGroup");
43 launchSpecification.setSecurityGroups(securityGroups);

45 // Add the launch specification.
46 requestRequest.setLaunchSpecification(launchSpecification);
```
// Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);

Persistent vs. One-Time Requests

When building a Spot request, you can specify several optional parameters. The first is whether your request is one-time only or persistent. By default, it is a one-time request. A one-time request can be fulfilled only once, and after the requested instances are terminated, the request will be closed. A persistent request is considered for fulfillment whenever there is no Spot Instance running for the same request. To specify the type of request, you simply need to set the Type on the Spot request. This can be done with the following code.

```java
1 // Retrieves the credentials from an AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
            GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

15 // Initializes a Spot Instance request
RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

    // Request 1 x t1.micro instance with a bid price of $0.03.
    requestRequest.setSpotPrice("0.03");
20 requestRequest.setInstanceCount(Integer.valueOf(1));

    // Set the type of the bid to persistent.
    requestRequest.setType("persistent");

25 // Set up the specifications of the launch. This includes the instance type (e.g., t1.micro) and the latest Amazon Linux AMI id available. Note, you should always use the latest Amazon Linux AMI id or another of your choosing.
    LaunchSpecification launchSpecification = new LaunchSpecification();
    launchSpecification.setImageId("ami-8clfece5");
30 launchSpecification.setInstanceType("t1.micro");

    // Add the security group to the request.
    ArrayList<String> securityGroups = new ArrayList<String>();
35 securityGroups.add("GettingStartedGroup");
    launchSpecification.setSecurityGroups(securityGroups);

    // Add the launch specification.
    requestRequest.setLaunchSpecification(launchSpecification);
```
Limiting the Duration of a Request

You can also optionally specify the length of time that your request will remain valid. You can specify both a starting and ending time for this period. By default, a Spot request will be considered for fulfillment from the moment it is created until it is either fulfilled or canceled by you. However you can constrain the validity period if you need to. An example of how to specify this period is shown in the following code.

```java
// Retrieves the credentials from an AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
        GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

// Initializes a Spot Instance request
RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

// Request 1 x t1.micro instance with a bid price of $0.03.
requestRequest.setSpotPrice("0.03");
requestRequest.setInstanceCount(Integer.valueOf(1));

// Set the valid start time to be two minutes from now.
Calendar cal = Calendar.getInstance();
    cal.add(Calendar.MINUTE, 2);
requestRequest.setValidFrom(cal.getTime());

// Set the valid end time to be two minutes and two hours from now.
    cal.add(Calendar.HOUR, 2);
requestRequest.setValidUntil(cal.getTime());

// Set up the specifications of the launch. This includes
// the instance type (e.g., t1.micro)

// and the latest Amazon Linux AMI id available.

// Note, you should always use the latest Amazon 
// Linux AMI id or another of your choosing.
LaunchSpecification launchSpecification = new LaunchSpecification();
launchSpecification.setImageId("ami-8clfece5");
launchSpecification.setInstanceType("t1.micro");

// Add the security group to the request.
ArrayList<String> securityGroups = new ArrayList<String>();
    securityGroups.add("GettingStartedGroup");
```
launchSpecification.setSecurityGroups(securityGroups);

// Add the launch specification.
requestRequest.setLaunchSpecification(launchSpecification);

// Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);

Grouping Your Amazon EC2 Spot Instance Requests

You have the option of grouping your Spot Instance requests in several different ways. We'll look at the benefits of using launch groups, Availability Zone groups, and placement groups.

If you want to ensure your Spot Instances are all launched and terminated together, then you have the option to leverage a launch group. A launch group is a label that groups a set of bids together. All instances in a launch group are started and terminated together. Note, if instances in a launch group have already been fulfilled, there is no guarantee that new instances launched with the same launch group will also be fulfilled. The following example shows how to set a launch group.

1 // Retrieves the credentials from an AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
        GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

15 // Initializes a Spot Instance request
RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

// Request 5 x t1.micro instance with a bid price of $0.03.
requestRequest.setSpotPrice("0.03");

20 requestRequest.setInstanceCount(Integer.valueOf(5));

// Set the launch group.
requestRequest.setLaunchGroup("ADVANCED-DEMO- LAUNCH-GROUP");

25 // Set up the specifications of the launch. This includes
// the instance type (e.g., t1.micro) and the latest Amazon Linux
// AMI id available. Note, you should always use the latest
// Amazon Linux AMI id or another of your choosing.
LaunchSpecification launchSpecification = new LaunchSpecification();

30 launchSpecification.setImageId("ami-8c1fece5");
launchSpecification.setInstanceType("t1.micro");

// Add the security group to the request.
ArrayList<String> securityGroups = new ArrayList<String>();
35  securityGroups.add("GettingStartedGroup");
    launchSpecification.setSecurityGroups(securityGroups);

    // Add the launch specification.
    requestRequest.setLaunchSpecification(launchSpecification);
40
    // Call the RequestSpotInstance API.
    RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);

If you want to ensure that all instances within a request are launched in the same Availability Zone, and you don’t care which one, you can leverage Availability Zone groups. An Availability Zone group is a label that groups a set of instances together in the same Availability Zone. All instances that share an Availability Zone group and are fulfilled at the same time will start in the same Availability Zone. An example of how to set an Availability Zone group follows.

1 // Retrieves the credentials from an AWSCredentials.properties file.
    AWSCredentials credentials = null;
    try {
        credentials = new PropertiesCredentials(
            GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
        } catch (IOException e1) { System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
        System.out.println(e1.getMessage());
        System.exit(-1);
10    }

15    // Create the AmazonEC2Client object so we can call various APIs.
    AmazonEC2 ec2 = new AmazonEC2Client(credentials);

20    // Initializes a Spot Instance request
    RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

    // Request 5 x t1.micro instance with a bid price of $0.03.
    requestRequest.setSpotPrice("0.03");
25    requestRequest.setInstanceCount(Integer.valueOf(5));

    // Set the Availability Zone group.
    requestRequest.setAvailabilityZoneGroup("ADVANCED-DEMO-A2-GROUP");

30    // Set up the specifications of the launch. This includes the instance type (e.g., t1.micro) and the latest Amazon Linux AMI id available.
    // Note, you should always use the latest Amazon Linux AMI id or another of your choosing.
    LaunchSpecification launchSpecification = new LaunchSpecification();

    launchSpecification.setImageId("ami-8c1fece5");

    // Add the security group to the request.
    ArrayList<String> securityGroups = new ArrayList<String>();
35    securityGroups.add("GettingStartedGroup");
    launchSpecification.setSecurityGroups(securityGroups);

    // Add the launch specification.
requestRequest.setLaunchSpecification(launchSpecification);

// Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);

You can specify an Availability Zone that you want for your Spot Instances. The following code example shows how to set an Availability Zone.

// Retrieves the credentials from an AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
            GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

// Initializes a Spot Instance request
RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

// Request 1 x t1.micro instance with a bid price of $0.03.
requestRequest.setSpotPrice("0.03");
requestRequest.setInstanceCount(Integer.valueOf(1));

// Set up the specifications of the launch. This includes the instance type (e.g., t1.micro) and the latest Amazon Linux AMI id available. Note, you should always use the latest Amazon Linux AMI id or another of your choosing.
LaunchSpecification launchSpecification = new LaunchSpecification();
launchSpecification.setImageId("ami-8c1fece5");
launchSpecification.setInstanceType("t1.micro");

// Add the security group to the request.
ArrayList<String> securityGroups = new ArrayList<String>();
securityGroups.add("GettingStartedGroup");
launchSpecification.setSecurityGroups(securityGroups);

// Set up the Availability Zone to use. Note we could retrieve the Availability Zones using the ec2.describeAvailabilityZones() API.
// For this demo, we will just use us-east-1a.
SpotPlacement placement = new SpotPlacement("us-east-1b");

launchSpecification.setPlacement(placement);

// Add the launch specification.
requestRequest.setLaunchSpecification(launchSpecification);

// Call the RequestSpotInstance API.

Lastly, you can specify a placement group if you are using High Performance Computing (HPC) Spot instances, such as cluster compute instances or cluster GPU instances. Placement groups provide you with lower latency and high-bandwidth connectivity between the instances. The following example shows how to set a placement group.

```java
// Retrieves the credentials from an AWSCredentials.properties file.
AWSCredentials credentials = null;
try {
    credentials = new PropertiesCredentials(
        GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
} catch (IOException e1) {
    System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
    System.out.println(e1.getMessage());
    System.exit(-1);
}

// Create the AmazonEC2Client object so we can call various APIs.
AmazonEC2 ec2 = new AmazonEC2Client(credentials);

// Initializes a Spot Instance request
RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

// Request 1 x t1.micro instance with a bid price of $0.03.
requestRequest.setSpotPrice("0.03");
requestRequest.setInstanceCount(Integer.valueOf(1));

// Set up the specifications of the launch. This includes the instance type (e.g., t1.micro) and the latest Amazon Linux AMI id available.
// Note, you should always use the latest Amazon Linux AMI id or another of your choosing.
LaunchSpecification launchSpecification = new LaunchSpecification();
launchSpecification.setImageId("ami-8c1fece5");
launchSpecification.setInstanceType("t1.micro");

// Add the security group to the request.
ArrayList<String> securityGroups = new ArrayList<String>();
securityGroups.add("GettingStartedGroup");
launchSpecification.setSecurityGroups(securityGroups);

// Add the placeholder group to use with whatever name you desire.
// For this demo, we will just use "ADVANCED-DEMO-PLACEMENT-GROUP".
SpotPlacement placement = new SpotPlacement();
placement.setGroupName("ADVANCED-DEMO-PLACEMENT-GROUP");
launchSpecification.setPlacement(placement);

// Add the launch specification.
requestRequest.setLaunchSpecification(launchSpecification);

// Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);
```
All of the parameters shown in this section are optional. It is also important to realize that most of these parameters—with the exception of whether your bid is one-time or persistent—can reduce the likelihood of bid fulfillment. So, it is important to leverage these options only if you need them. All of the preceding code examples are combined into one long code sample, which can be found in the com.amazonaws.codesamples.advanced.InlineGettingStartedCodeSampleApp.java class.

**How to Persist a Root Partition After Interruption or Termination**

One of the easiest ways to manage interruption of your Spot instances is to ensure that your data is checkpointed to an Amazon Elastic Block Store (Amazon EBS) volume on a regular cadence. By checkpointing periodically, if there is an interruption you will lose only the data created since the last checkpoint (assuming no other non-idempotent actions are performed in between). To make this process easier, you can configure your Spot Request to ensure that your root partition will not be deleted on interruption or termination. We've inserted new code in the following example that shows how to enable this scenario.

In the added code, we create a `BlockDeviceMapping` object and set its associated Elastic Block Storage (EBS) to an EBS object that we've configured to not be deleted if the Spot Instance is terminated. We then add this `BlockDeviceMapping` to the `ArrayList` of mappings that we include in the launch specification.

```java
1 // Retrieves the credentials from an AWSCredentials.properties file.
   AWSCredentials credentials = null;
   try {
      credentials = new PropertiesCredentials(
         GettingStartedApp.class.getResourceAsStream("AwsCredentials.properties"));
   } catch (IOException e1) {
      System.out.println("Credentials were not properly entered into AwsCredentials.properties.");
      System.out.println(e1.getMessage());
      System.exit(-1);
   }

   // Create the AmazonEC2Client object so we can call various APIs.
   AmazonEC2 ec2 = new AmazonEC2Client(credentials);

   // Initializes a Spot Instance request
   RequestSpotInstancesRequest requestRequest = new RequestSpotInstancesRequest();

   // Request 1 x t1.micro instance with a bid price of $0.03.
   requestRequest.setSpotPrice("0.03");
   requestRequest.setInstanceCount(Integer.valueOf(1));

   // Set up the specifications of the launch. This includes the instance type (e.g., t1.micro) and the latest Amazon Linux AMI id available.
   LaunchSpecification launchSpecification = new LaunchSpecification();
   launchSpecification.setImageId("ami-8c1fece5");
   launchSpecification.setInstanceType("t1.micro");

   // Add the security group to the request.
   ArrayList<String> securityGroups = new ArrayList<String>();
   securityGroups.add("GettingStartedGroup");
   launchSpecification.setSecurityGroups(securityGroups);
```
// Create the block device mapping to describe the root partition.
BlockDeviceMapping blockDeviceMapping = new BlockDeviceMapping();
    blockDeviceMapping.setDeviceName("/dev/sda1");

    // Set the delete on termination flag to false.
EbsBlockDevice ebs = new EbsBlockDevice();
ebs.setDeleteOnTermination(Boolean.FALSE);
    blockDeviceMapping.setEbs(ebs);

    // Add the block device mapping to the block list.
ArrayList<BlockDeviceMapping> blockList = new ArrayList<BlockDeviceMapping>();
    blockList.add(blockDeviceMapping);

    // Set the block device mapping configuration in the launch specifications.
    launchSpecification.setBlockDeviceMappings(blockList);

    // Add the launch specification.
    requestRequest.setLaunchSpecification(launchSpecification);

    // Call the RequestSpotInstance API.
RequestSpotInstancesResult requestResult = ec2.requestSpotInstances(requestRequest);

Assuming you wanted to re-attach this volume to your instance on startup, you can also use the block
device mapping settings. Alternatively, if you attached a non-root partition, you can specify the Amazon
EBS volumes you want to attach to your Spot Instance after it resumes. You do this simply by specifying
a snapshot ID in your EbsBlockDevice and alternative device name in your BlockDeviceMapping
objects. By leveraging block device mappings, it can be easier to bootstrap your instance.

Using the root partition to checkpoint your critical data is a great way to manage the potential for interruption
of your instances. For more methods on managing the potential of interruption, please visit the Managing
Interruption video.

How to Tag Your Spot Requests and Instances

Adding tags to EC2 resources can simplify the administration of your cloud infrastructure. A form of
metadata, tags can be used to create user-friendly names, enhance searchability, and improve coordination
between multiple users. You can also use tags to automate scripts and portions of your processes. For
more information, see Tagging Your Amazon EC2 Resources (p. 610).

To add tags to your resources, you need to tag them after they have been requested. Specifically, you
must add a tag after a Spot request has been submitted or after the RunInstances call has been
performed. The following code example illustrates adding tags.

Tags are a simple first step toward making it easier to manage your own cluster of instances. To read more about tagging Amazon EC2 resources, see Tagging Your Amazon EC2 Resources (p. 610).

**Bringing It All Together**

To bring this all together, we provide a more object-oriented approach that combines the steps we showed in this tutorial into one easy to use class. We instantiate a class called `Requests` that performs these actions. We also create a `GettingStartedApp` class, which has a main method where we perform the high-level function calls.

The complete source code is available for download at GitHub.

Congratulations! You've completed the Advanced Request Features tutorial for developing Spot Instance software with the AWS SDK for Java.

**Starting Clusters on Spot Instances**

Grids are a form of distributed computing that enable a user to leverage multiple instances to perform parallel computations. Customers—such as Numerate, Scribd, and the University of Barcelona/University of Melbourne—use grid computing with Spot Instances because this type of architecture can take advantage of Spot Instance’s built-in elasticity and low prices to get work done faster at a more cost-effective price.
To get started, a user will break down the work into discrete units called jobs, and then submit that work to a “master node.” These jobs will be queued up, and a process called a “scheduler” will distribute that work out to other instances in the grid, called “worker nodes.” After the result is computed by the worker node, the master node is notified, and the worker node can take the next operation from the queue. If the job fails or the instance is interrupted, the job will automatically be re-queued by the scheduler process.

As you work to architect your application, it is important to choose the appropriate amount of work to be included in your job. We recommend breaking your jobs down into a logical grouping based on the time it would take to process. Typically, you will want to create a workload size less than an hour, so that if you have to process the workload again, it doesn’t cost you additional money (you don’t pay for the hour if we interrupt your instance).

Many customers use a Grid scheduler, such as Oracle Grid Engine or UniCloud, to set up a cluster. If you have long-running workloads, the best practice is to run the master node on On-Demand or Reserved Instances, and run the worker nodes on Spot or a mixture of On-Demand, Reserved, and Spot Instances. Alternatively, if you have a workload that is less than an hour or you are running a test environment, you may want to run all of your instances on Spot. No matter the setup, we recommend that you create a script to automatically re-add instances that may be interrupted. Some existing tools—StarCluster, for example—can help you manage this process.

**Quick Look: How to Launch a Cluster on Spot Video**

Chris Dagdigian, from AWS Solution Provider BioTeam, provides a quick overview of how to start a cluster from scratch in about 10 to 15 minutes on Amazon EC2 Spot Instances using StarCluster. StarCluster is an open source tool created by a lab at MIT that makes it easy to set up a new Oracle Grid Engine cluster. In this video, Chris walks through the process of installing, setting up, and running simple jobs on a cluster. Chris also leverages Spot Instances, so that you can potentially get work done faster and potentially save between 50 percent to 66 percent: How to Launch a Cluster on Spot.
Reserved Instances

The Amazon Elastic Compute Cloud (Amazon EC2) Reserved Instances pricing model enables you to reserve capacity for your EC2 instances and lower your average instance cost. With Reserved Instances, you pay a low, one-time fee for the capacity reservation and then receive a significant discount on the hourly charge for your instances. When you want to use your reserved capacity, you launch an EC2 instance with the same configuration as the reserved capacity that you purchased. It does not matter how the instances are launched: you can launch them directly as On-Demand instances, through Auto Scaling, or you can use another process. Amazon Web Services (AWS) will automatically apply the discounted hourly rate that is associated with your capacity reservation. You are charged the discounted hourly rate for your EC2 instance for as long as you own the Reserved Instance.

When the term of your Reserved Instance ends, you can continue using the EC2 instance without interruption. However, you will now be charged at the On-Demand rate. For information about launching On-Demand instances, see Launch Your Instance (p. 300). For information about launching instances using Auto Scaling, see the Auto Scaling Developer Guide.

Reserved Instances can provide substantial savings over owning your own hardware or running only On-Demand instances, and they can help assure that the capacity you need is available to you when you require it.

To purchase an Amazon EC2 Reserved Instance, you must select an instance type (such as m1.small), platform (Linux/UNIX, Windows, or Windows with SQL Server), location (region and Availability Zone), and term (either one year or three years). If you want your Reserved Instance to run on a specific Linux/UNIX platform, you must identify that platform when you purchase the reserved capacity. Then, when you’re ready to use the Reserved Instance that you purchased, you must choose an Amazon Machine Image (AMI) that runs that specific Linux/UNIX platform, along with any other specifications you identified during the purchase.

For example, if you require a one-year, SUSE Linux, m1.medium Reserved Instance in the Singapore region, purchasing a one-year, Linux/UNIX, m1.medium Reserved Instance in the Singapore region will not give you the capacity reservation and pricing benefit. Both your Reserved Instance purchase and the instance you launch must specify the same SUSE Linux product platform.

Reserved Instance Overview

The following information will help you get started working with Amazon EC2 Reserved Instances:

- Complete all the prerequisite tasks first—such as registration, signing up, and installing the tools—so you can start working with Reserved Instances. For more information, see Getting Started with Reserved Instances (p. 199).
- Before you buy and sell Reserved Instances, you can learn more about them by reading Steps for Using Reserved Instances (p. 200).
- Standard one- and three-year terms for Reserved Instances are available for purchase from AWS, and non-standard terms are available for purchase from third-party resellers through the Reserved Instance Marketplace.
- Optimize your Reserved Instance costs by selecting the pricing model that best matches how often you plan to use your instances. For more information, see Choosing Reserved Instances Based on Your Usage Plans (p. 204).
• Learn more about the pricing benefit of Reserved Instances. For more information, see Understanding the Pricing Benefit of Reserved Instances (p. 210).
• Understand Reserved Instance pricing tiers and how to take advantage of discount pricing. For more information, see Understanding Reserved Instance Pricing Tiers (p. 205).
• You can sell your unused Reserved Instances in the Reserved Instance Marketplace. The Reserved Instance Marketplace makes it possible for sellers who have Reserved Instances that they no longer need to find buyers who are looking to purchase additional capacity. Reserved Instances bought and sold through the Reserved Instance Marketplace work like any other Reserved Instances. For more information, see Reserved Instance Marketplace (p. 212).

For a checklist that summarizes requirements for working with Reserved Instances and the Reserved Instance Marketplace, see Requirements Checklist for Reserved Instances (p. 266).

You can use Amazon Elastic Compute Cloud (Amazon EC2) Reserved Instances to reserve capacity for your instances and get the benefits of lower-cost computing. With Reserved Instances you pay a low, one-time fee and in turn receive a significant discount on the hourly charge for your instance. Reserved Instances can provide substantial savings over owning your own hardware or running only On-Demand instances, as well as help assure that the capacity you need is available to you when you require it. This topic takes you through the basic information you need to get started with Reserved Instances.

Get Set Up

Before you get started working with Reserved Instances, you should complete the following tasks:

• Sign up.
To work with Reserved Instances, read and complete the instructions described in Getting Started with Amazon EC2 Linux Instances (p. 24), which provides information on signing up for your Amazon EC2 account and credentials.

- Install the tools.

You can use the Amazon EC2 tools—AWS Management Console, Amazon EC2 Command Line Interface (CLI) tools, or the Amazon EC2 API—to work with EC2 Reserved Instances and search for offerings. For more information, see Tools for Working with Reserved Instances (p. 202).

If you want to start working with Reserved Instances using specific tools, see AWS Management Console (p. 202), the Command Line Interface Tools (p. 202), or the API (p. 203).

**Steps for Using Reserved Instances**

There are five sets of steps to follow when you use Reserved Instances. You can purchase Amazon EC2 Reserved Instances, and then you can launch them. You can view the Reserved Instances you have, modify them, and you can sell unused Reserved Instances in the Reserved Instance Marketplace. (Restrictions apply. For information, see Requirements Checklist for Reserved Instances (p. 266).) This section describes purchasing, launching, viewing, modifying, and selling Reserved Instances.

You can use the AWS Management Console, the Amazon EC2 CLI tools, or the Amazon EC2 API to perform any of these tasks. Before you get started, you need to set up the prerequisite accounts and tools. For more information, see Get Set Up (p. 199).

1. Purchase.
   a. Determine how much capacity you want to reserve. Specify the following criteria for your instance reservation.
      - Platform (for example, Linux/UNIX).

      **Note**
      When you want your Reserved Instance to run on a specific Linux/UNIX platform, you must identify the specific platform when you purchase the reserved capacity. Then, when you launch your instance with the intention of using the reserved capacity you purchased, you must choose the Amazon Machine Image (AMI) that runs that specific Linux/UNIX platform, along with any other specifications you identified during the purchase.
      - Instance type (for example, m1.small).
      - Term (time period) over which you want to reserve capacity (one or three years).
      - Tenancy specification, if you want to reserve capacity for your instance to run in single-tenant hardware (dedicated tenancy, as opposed to shared).
      - Region and Availability Zone where you want to run the instance.
   b. Choose the offering type that best addresses how much you want to pay and how often you plan to run your instances.
      - Heavy Utilization
      - Medium Utilization
      - Light Utilization

      For more information about these offering types, see Choosing Reserved Instances Based on Your Usage Plans (p. 204).
   c. Search for offerings that meet the criteria you specified.
   d. Purchase offerings that fulfill your requirements.

   For more information, see Purchasing Reserved Instances (p. 217).

2. Launch.
To use your Reserved Instance, launch an On-Demand EC2 instance with the same criteria as your Reserved Instance (the region, Availability Zone, instance type, and platform specified when you purchased your Reserved Instance). See step 1.

**Note**
Reserved Instance pricing benefits and capacity reservations automatically apply to any running EC2 instances you have that aren’t already covered by a reservation.

For more information, see [Launch Your Instance](p. 300).

3. **View.**

You can view the Reserved Instances that you own or that are available to your account, and confirm that your instances are running as specified.

For more information, see [Obtaining Information About Your Reserved Instances](p. 225).

4. **Modify.**

You can modify your Reserved Instances by moving them between Availability Zones within the same region, changing their instance type to another instance type in the same instance family (e.g., the M1 instance family), or modifying the network platform of the Reserved Instances between EC2-VPC and EC2-Classic.

For more information, see [Modifying Your Reserved Instances](p. 230).

5. **Sell Reserved Instance capacity that you no longer need.**

   a. Register as a seller in the Reserved Instance Marketplace using the Seller Registration wizard. For more information, see [Registering as a Seller](p. 241).

      **Note**
      Not every customer can sell in the Reserved Instance Marketplace and not all Reserved Instances can be sold in the Reserved Instance Marketplace. For information, see [Requirements Checklist for Reserved Instances](p. 266).

   b. Decide on a price for the Reserved Instances that you want to sell. For more information, see [Pricing Your Reserved Instances](p. 246).

   c. List your Reserved Instances. For more information, see [Listing Your Reserved Instance](p. 246).

   d. Find out how you get paid when your Reserved Instances are sold. For more information, see [Getting Paid](p. 266).

**Using Reserved Instances in Amazon VPC**

To launch Reserved Instances in Amazon Virtual Private Cloud (Amazon VPC), you must either have an account that supports a default VPC or you must purchase an Amazon VPC Reserved Instance.

If your account does not support a default VPC, you must purchase an Amazon VPC Reserved Instance by selecting a platform that includes Amazon VPC in its name. For more information, see [Detecting Your Supported Platforms and Whether You Have a Default VPC](p. 266). For information about Amazon VPC, see [What is Amazon VPC?](in the Amazon Virtual Private Cloud User Guide).

If your account supports a default VPC, the list of platforms available does not include Amazon VPC in its name because all platforms have default subnets. In this case, if you launch an instance with the same configuration as the capacity you reserved and paid for, that instance is launched in your default VPC and the capacity reservation and billing benefits are applied to your instance. For information about default VPCs, see [Your Default VPC and Subnets](in the Amazon Virtual Private Cloud User Guide).

You can also choose to purchase Reserved Instances that are physically isolated at the host hardware level by specifying dedicated as the instance tenancy. For more information about Dedicated Instances, see [Using EC2 Dedicated Instances Within Your VPC](in the Amazon Virtual Private Cloud User Guide).
Tools for Working with Reserved Instances

You can use the AWS Management Console (p. 202), the Command Line Interface Tools (p. 202), or the API (p. 203) to list or search for available Amazon EC2 Reserved Instances, purchase reserved capacity, manage your Reserved Instance, and sell your unused Reserved Instances.

If you use the CLI tools, first you should read and complete the instructions described in Setting Up the Amazon EC2 Tools. The topic walks you through setting up your environment for use with the CLI tools.

AWS Management Console

The AWS Management Console has tools specifically designed for Reserved Instances tasks. You can find them in the Amazon EC2 console. You will also find general tools that you can use to manage the instances launched when you use your Reserved Instances.

- **The Reserved Instances page** is where you work with your Reserved Instances.

  ![Reserved Instances Page](image)

- **Use the Purchase Reserved Instances page** to specify the details of the Reserved Instances you want to purchase.

  ![Purchase Reserved Instances Page](image)

- **Use the Instances page** to launch your Reserved Instances and manage them.

Command Line Interface Tools

To purchase Reserved Instances, or sell them in the Reserved Instance Marketplace, you can use Amazon EC2 command line interface (CLI) tools specifically designed for these tasks. To manage the instances when your Reserved Instances are launched, use the same commands in the CLI tools that you use for any other Amazon EC2 instances.
The following table lists the commands in the CLI tools that you use specifically for Reserved Instances tasks.

<table>

For information about CLI commands, see the Amazon Elastic Compute Cloud Command Line Reference.

API

To purchase Reserved Instances, you use API calls specifically designed for these tasks. To manage the instances when your Reserved Instances are launched, use the same API calls that you use for any other Amazon EC2 instances.

The following table lists the API calls you use for Reserved Instances tasks.

Reserved Instance Fundamentals

This section discusses fundamental concepts that can help you optimize the benefits of Reserved Instances, and use and manage them effectively.

• Choosing Reserved Instances Based on Your Usage Plans (p. 204)—Select the pricing model that best matches how often you plan to use your instances.

• Understanding Reserved Instance Pricing Tiers (p. 205)—Take advantage of the Reserved Instances pricing tier discounts in a region, when the total upfront list price of your Reserved Instances in the region is $250,000 USD or more.

• Understanding the Pricing Benefit of Reserved Instances (p. 210)—Learn how the Reserved Instances pricing benefits are applied.

• Reserved Instance Marketplace (p. 212)—Understand the flexibility provided by the Reserved Instance Marketplace to AWS customers who can sell the remainder of their Reserved Instances when their needs change, or buy Reserved Instances with less than the full standard terms from other AWS customers.

Choosing Reserved Instances Based on Your Usage Plans

You can select a Reserved Instance fee structure based on how often you plan to use your instance. We offer three Reserved Instance types to address your projected utilization of the instance: Heavy Utilization, Medium Utilization, or Light Utilization. (To use these Reserved Instance types, make sure you have API version 2011-11-01 or later.)

Heavy Utilization Reserved Instances can be used to enable workloads that have a consistent baseline of capacity, or they can run steady-state workloads. Heavy Utilization Reserved Instances require the highest upfront commitment. However, if you plan to run your Reserved Instances around 35 percent of the time or more for a three-year term, you may be able to earn the largest savings (up to around 65 percent off of the On-Demand price if your instance utilization is 100 percent) of any of the offering types. Unlike other Reserved Instances offering types, with Heavy Utilization Reserved Instances, you pay a one-time fee, followed by a lower hourly fee for the duration of the term regardless of whether or not your instance is running.

Medium Utilization Reserved Instances are the best option if you plan to use your Reserved Instances a substantial amount of the time, but want either a lower one-time fee or the flexibility to stop paying for your instance when you shut it off. Medium Utilization is a cost-effective option when you plan to run your Reserved Instances approximately between 19 percent and 35 percent of the time over the Reserved Instance term. This option can save you up to 59 percent off of the On-Demand price. With Medium Utilization Reserved Instances, you pay a slightly higher one-time fee than with Light Utilization Reserved Instances, but you receive lower hourly usage rates when you run an instance. (This offering type is equivalent to the Reserved Instance offering available before API version 2011-11-01.)

Light Utilization Reserved Instances are ideal for periodic workloads that run only a couple of hours a day or a few days per week. Using Light Utilization Reserved Instances, you pay a one-time fee followed by a discounted hourly usage fee when your instance is running. You start saving when your instance is running approximately between 11 percent and 19 percent of the time over the Reserved Instance term, and you can save up to 49 percent off of the On-Demand rates over the entire term of your Reserved Instance.

Note

With Light Utilization and Medium Utilization Reserved Instances, you pay a one-time upfront fee and then only pay the hourly price when you use the instance. With Heavy Utilization Reserved Instances, you pay a one-time upfront fee and commit to paying an hourly rate for every hour of the Reserved Instance’s term whether or not you use it.
Remember that discounted usage fees for Reserved Instance purchases are tied to your specifications of type and Availability Zone of your instance. If you shut down a running EC2 instance on which you have been getting a discounted rate as a result of a Reserved Instance purchase, and the term of the Reserved Instance has not yet expired, you will continue to get the discounted rate if you launch another instance with the same specifications during the remainder of the term.

The following table summarizes the differences between the Reserved Instances offering types.

### Understanding Reserved Instance Pricing Tiers

To qualify for Amazon Elastic Compute Cloud (EC2) Reserved Instances pricing tier discounts in a region, the total upfront list price of your Reserved Instances in the region must be $250,000 USD or more. When your account qualifies for a discount pricing tier, it will automatically receive discounts on upfront and usage fees for all Reserved Instance purchases that you make within that tier level from that point on.

This section introduces you to Reserved Instances pricing tiers and how to take advantage of the pricing tier discounts.

- What Are the Reserved Instance Pricing Tiers? (p. 206)
- Current Limitations (p. 206)
- Determining Your Pricing Tier Level (p. 206)
- How Do Pricing Tier Discounts Get Applied? (p. 208)
For information about how the pricing benefit of Reserved Instances is applied, see Understanding the Pricing Benefit of Reserved Instances (p. 210). For information about Reserved Instances pricing, see Amazon EC2 Reserved Instance Pricing.

What Are the Reserved Instance Pricing Tiers?

The following table lists the qualifications for each pricing tier and the discount that is applied when the total upfront list price of your active Reserved Instances in a region crosses into the range of that pricing tier.

Current Limitations

The following limitations currently apply to Reserved Instances pricing tiers:

- Amazon EC2 Reserved Instance purchases are the only purchases that will apply toward your Amazon EC2 Reserved Instance pricing tier discounts. And the Amazon EC2 Reserved Instance pricing tiers and related discounts apply only to purchases of Amazon EC2 Reserved Instances.
- Amazon EC2 Reserved Instance pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard or Windows with SQL Server Web.
- Amazon EC2 Reserved Instances purchased as part of a tiered discount cannot be sold in the Reserved Instance Marketplace. For more information about the Reserved Instance Marketplace, see Reserved Instance Marketplace (p. 212).

For a checklist that summarizes requirements for working with Reserved Instances and the Reserved Instance Marketplace, see Requirements Checklist for Reserved Instances (p. 266).

Determining Your Pricing Tier Level

To determine which Reserved Instance pricing tier applies to you in a particular region, compare the sum of your Reserved Instances’ upfront list prices to the total upfront list price required for the pricing tier. List price is the undiscounted Reserved Instance price that you see in the AWS Management Console or the AWS marketing website. Keep in mind that if the price of Reserved Instances drops after you buy Reserved Instances, that price drop might not be reflected in the undiscounted Reserved Instance price of your Reserved Instances.

List price is not the same as paid price. Paid price is the actual amount that you paid for the Reserved Instances. (The term paid price is the same as the term fixed price that you see when you use Reserved Instance tools in the AWS Management Console, command line interface (CLI), or the API.) If the Reserved Instance was purchased at a discount, the paid price will be lower than the list price. If the Reserved Instance was purchased without a discount, the paid price will equal the list price. So, if you purchased your Reserved Instances without discounts, you can use the fixed price value in the console, the CLI, or the API to determine which pricing tier your purchase falls under.
Note
In the Amazon EC2 console, you might need to turn on the display of the **Fixed Price** column
by clicking **Show/Hide** in the top right corner.

Assuming you purchased your Reserved Instances without discounts, you can determine the pricing tier
for your account by calculating the total fixed price for all your Reserved Instances in a region. To do this
using the console, calculate the sum of the amounts in the **Fixed Price** column.

Using the AWS CLI, Amazon EC2 CLI, or the Amazon EC2 API, you can determine the pricing tier of
your account by calculating the sum of the **fixed price** values returned by the `aws ec2
describe-reserved-instances` AWS CLI command, the `ec2-describe-reserved-instances
EC2` command, or the `DescribeReservedInstances` action, respectively.

Your AWS CLI command should look like the following example:

```
$ aws ec2 describe-reserved-instances
```

Amazon EC2 returns output similar to the following example:

```
{
   "ReservedInstances": [

For an example using the Amazon EC2 CLI command, see ec2-describe-reserved-instances. For an example using the Amazon EC2 API action, see DescribeReservedInstances.

How Do Pricing Tier Discounts Get Applied?

If a single purchase of Reserved Instances in a region takes you over the threshold of a discount tier, then the portion of that purchase that is above the price threshold will be charged at the discounted rate. Refer to the table in the previous section for tiers and discount price points.

**Note**

Amazon EC2 Reserved Instance purchases are the only purchases that determine your Amazon EC2 Reserved Instance pricing tiers, and the Amazon EC2 Reserved Instance pricing tiers apply only to Amazon EC2 Reserved Instance purchases.

Here's an example that shows you the discount effect of a purchase of Reserved Instances that crosses the discount tier threshold. Let's assume you currently have $200,000 worth of active Reserved Instances in the us-east-1 region. You purchase 75 Reserved Instances at the list price of $1,000 each. That's a total of $75,000, which brings the total amount you have paid for active Reserved Instances to $275,000. Because the discount pricing threshold is $250,000, the first $50,000 of your new purchase would not receive a discount. The remaining $25,000, which exceeds the discount pricing threshold, would be discounted by 5 percent ($1,250). This means you will only be charged $23,750 for the remainder of your purchase (25 instances), and you will be charged discounted usage rates for those 25 Reserved Instances. (However, keep in mind that your total upfront—*undiscounted*—list price is still $275,000.)

After the total upfront list price of your active Reserved Instances in a region crosses into the discount pricing tier, any future purchase of Reserved Instances in that region will be charged at a discounted rate. As long as your total list price stays above the price point for the discount tier, all future purchases of Reserved Instances in that region will be discounted. If your total list price falls below that price point for the discount tier—for example, if some of your Reserved Instances expire—succeeding purchases of Reserved Instances in the region will not be discounted. However, you will continue to get the discount against the already purchased Reserved Instances that originally were within the discount pricing tier.

If your account is part of a consolidated billing account, you can benefit from the Reserved Instance pricing tiers. A consolidated billing account aggregates into a single list price the list prices of all of the active Reserved Instances accounts in a region that are part of the consolidated billing account. When the total list price of active Reserved Instances for the consolidated billing account reaches the discount tier level, any Reserved Instances purchased after this point by any member of the consolidated account will be charged at the discounted rate (as long as the total list price for that consolidated account stays above the discount tier price point).

Here's how Reserved Instance purchases work with consolidated billing: Let's assume that two accounts—A and B—are part of a consolidated billing account. All the active Reserved Instances in the consolidated billing account are in one region. Account A has Reserved Instances worth $135,000; Account B has Reserved Instances worth $115,000. The total upfront cost of the consolidated bill of accounts A and B is $250,000. Remember, $250,000 is the discount pricing threshold. This means that when either or both of the A and B accounts purchase additional Reserved Instances, the cost of the new purchases will be discounted by 5 percent. So, when account B purchases Reserved Instances at a list price of $15,000, the consolidated account will only be charged $14,250 for the new Reserved Instances ($15,000 minus the 5 percent discount of $750 equals $14,250), and account B will be charged discounted usage rates for those new Reserved Instances.
For more information about how the benefits of Reserved Instances apply to consolidated billing accounts, see Reserved Instances and Consolidated Billing (p. 212).

**Purchasing at a Discount Tier Price**

When you purchase Reserved Instances, Amazon EC2 will automatically apply any discounts to the part of your Reserved Instance purchase that falls within a discount tier. You don’t need to do anything differently, and you can purchase using any of the Amazon EC2 tools.

- AWS Management Console: Click the Purchase Reserved Instances button on the Reserved Instances page of the Amazon EC2 console.
- AWS CLI: Use the `aws ec2 purchase-reserved-instances-offering` command.
- Amazon EC2 CLI: Use the `ec2-purchase-reserved-instances-offering` command.
- Amazon EC2 API: Call the `PurchaseReservedInstancesOffering` action.

If your purchase crosses into a discounted pricing tier, the console, the `aws ec2 describe-reserved-instances` and `ec2-describe-reserved-instances` commands, or the `DescribeReservedInstances` action will show multiple entries for that purchase. You will see an entry for that part of the purchase that will be charged the regular Reserved Instance price, and another entry or entries for that part of the purchase that will be charged the applicable discounted rate.

Consequently, the Reserved Instance ID returned by your purchase CLI command or API action will be different from the actual ID of the new Reserved Instances. For more information, see Reserved Instance IDs (p. 210).

For example, let’s say that your account has a list price total of $245,000 in Reserved Instances in a region. You purchase more Reserved Instances at a total list price of $10,000. Remember that the threshold for the 5 percent discount tier is $250,000, so $5,000 of your purchase crosses into the discount tier. When the transaction is complete, the list you’ll get from the console, the CLI, or the API will show two reservations—a reservation for $5,000 at the undiscounted rate, and another for $4,750, which is the discounted price. The discount is 5 percent of $5,000 or $250.

The pricing discount applies to future purchases after the total list price cost of your active Reserved Instances reaches the discounted pricing tier. However, if some of your Reserved Instances expire and the total list price for your active Reserved Instances falls below the discounted pricing tier level, then the next purchase you make will be at the retail rates for Reserved Instances. To illustrate, let’s use the previous example: You currently have a list price total of $254,750 in Reserved Instances. $250,000 is at the undiscounted rate, and $4,750 is at the discounted rate. In two months, Reserved Instances worth $20,000 expire, bringing your total down to $234,750, which is below the threshold for the 5 percent discount tier. When you subsequently purchase $15,000 in Reserved Instances, you will be charged the retail rate. However, the $4,500 in Reserved Instances that you purchased earlier at the discounted rate will continue to be charged at the discounted rate.

The main point to keep in mind is that list price is the undiscounted price of the Reserved Instance at the time of purchase, while the fixed price value in the console, the AWS CLI, Amazon EC2 CLI, and the Amazon EC2 API is the paid price of all Reserved Instances purchased. The discount tier is based on list price.

Remember that when you purchase Reserved Instances, one of four possible scenarios will occur:

- Your purchase of Reserved Instances within a region is still below the discount threshold. This means that you don’t get a discount.
- Your purchase of Reserved Instances within a region crosses the threshold of the first discount tier. This means that the newly purchased Reserved Instances will go into the pending state while the purchase is processed. For this purchase, the Reserved Instances service will purchase Reserved Instances for you at two different rates: An amount at the undiscounted rate, and an amount at the discounted rate. It is important to understand that the Reserved Instance IDs you get back from the...
CLI or API when you use the purchase command will be different from the new Reserved Instance IDs that will actually be created at the completion of the purchase. These IDs are returned when you use the describe command. For an explanation of this difference, see the next section, Reserved Instance IDs (p. 210).

- Your entire purchase of Reserved Instances within a region is completely within one discount tier. This means that the newly purchased Reserved Instances will go into the pending state while the purchase is processed. For this purchase, the Reserved Instances service will purchase Reserved Instances at the appropriate discount level for you. It is important to understand that, as with the previous scenario, the Reserved Instance IDs you get back will be different from the new Reserved Instance IDs that will actually be created at the completion of the purchase. These IDs are returned when you use the describe command. For an explanation of this difference, see the next section, Reserved Instance IDs (p. 210).

- Your purchase of Reserved Instances within a region crosses from a lower discount tier to a higher discount tier. As with the previous scenario, this means that the newly purchased Reserved Instances will go into the pending state while the purchase is processed. For this purchase, the Reserved Instances service will purchase Reserved Instances for you at two different rates: An amount at the first or lower discounted rate, and an amount at the higher discounted rate. It is important to understand that the Reserved Instance IDs you get back will be different from the new Reserved Instance IDs that will actually be created at the completion of the purchase. For an explanation of this difference, see the next section, Reserved Instance IDs (p. 210).

Reserved Instance IDs

When your total purchase crosses one or more Reserved Instance discount pricing tiers, the Reserved Instance IDs returned by your purchase command can be different from the Reserved Instance IDs returned by the describe command that you call after the purchase is complete. What happens is that the Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier to a discounted tier, or from one discounted tier to another. There will be a Reserved Instance ID for each set of Reserved Instances in a tier.

Using the AWS CLI, here’s an example output showing the `aws ec2 describe-reserved-instances` command not recognizing the Reserved Instance ID `1ba8e2e3-edf1-43c3-b587-7742example`, which was returned by `aws ec2 purchase-reserved-instances-offering`.

```json
{
   "ReservedInstances": []
}
```

In this example, the Reserved Instance ID generated by the purchase command is an intermediate ID that is used while the purchase is being processed. Because your purchase crossed from the undiscounted tier (tier 0) to the first discounted tier (tier 1), the Reserved Instance service actually generates several Reserved Instance IDs: the intermediate Reserved Instance ID, a Reserved Instance ID for the Reserved Instances that you purchased at the undiscounted list price, and Reserved Instance IDs for the Reserved Instances that you purchased at the 5 percent discount rate.

Understanding the Pricing Benefit of Reserved Instances

When you purchase Reserved Instances, you get two benefits: a capacity reservation for a number of EC2 instances you will launch at some future time, and a discounted hourly fee. The rest of the experience of launching and working with Reserved Instances is the same as working with On-Demand EC2 instances.

This section discusses how Amazon EC2 applies the pricing benefit of Reserved Instances. For information about the Reserved Instances pricing tiers, see What Are the Reserved Instance Pricing Tiers? (p. 206). For information about Reserved Instances pricing, see Amazon EC2 Reserved Instance Pricing.
Applying the Pricing Benefit of Reserved Instances

With Reserved Instances, you pay an upfront fee for the capacity reservation on available Amazon EC2 instances based on the specifications (such as product platform, instance type, Availability Zone, etc.) that you defined during the purchase. After you purchase Reserved Instances, you can modify them as long as requirements for modifications are met and capacity exists. For information about modifying Reserved Instances, see Modifying Your Reserved Instances (p. 230). (You also can sell your unused Reserved Instances in the Reserved Instance Marketplace.)

In addition to the capacity reservation, you also get a discounted rate on the hourly fee for running On-Demand EC2 instances that are associated with the same account that purchased the Reserved Instances. For the discount to apply, the On-Demand instances must match the specifications for the Reserved Instances.

For example, let’s say user A is running the following ten On-Demand EC2 instances:

- (4) m1.small instances in Availability Zone us-east-1a
- (4) c1.medium instances in Availability Zone us-east-1b
- (2) c1.xlarge instances in Availability Zone us-east-1b

Then user A purchases the following six Reserved Instances:

- (2) m1.small instances in Availability Zone us-east-1a
- (3) c1.medium instances in Availability Zone us-east-1a
- (1) c1.xlarge instance in Availability Zone us-east-1b

When he purchases the Reserved Instances, user A pays an upfront fee for the capacity reservation so he can launch the six instances to his specifications when he needs them. In addition, he gets a discount on the hourly usage fees for the equivalent of six instances each month. Since he already has instances running when he purchases the Reserved Instances, Amazon EC2 will automatically apply the discounted hourly rates to the already running On-Demand instances that match the specifications for the Reserved Instances he purchased.

This is what happens:

- Amazon EC2 applies the discounted usage fee rate for two m1.small Reserved Instances that user A purchased to two of the four running m1.small Amazon EC2 instances in Availability Zone us-east-1a. The other two EC2 instances in Availability Zone us-east-1a will be charged at the current On-Demand rate.
- Amazon EC2 doesn’t apply discounted rates from the three c1.medium Reserved Instances that user A purchased because these c1.medium Reserved Instances are specified to run in a different Availability Zone from the zone currently running c1.medium Amazon EC2 instances. The four running c1.medium Amazon EC2 instances will be charged at the current On-Demand rate.
- If user A launches a c1.medium EC2 instance in Availability Zone us-east-1a, then Amazon EC2 will apply the Reserved Instance discounted usage fee rate to that instance.
- Amazon EC2 applies the discounted usage fee rate for one c1.xlarge Reserved Instance that user A purchased to one of the two running c1.xlarge Amazon EC2 instances in Availability Zone us-east-1b. The other c1.xlarge EC2 instance in Availability Zone us-east-1b will be charged at the current On-Demand rate.
In this example scenario, by purchasing the six Reserved Instances, user A saves on the hourly fee charged against two m1.small and one c1.xlarge On-Demand EC2 instances he had already running. At the same time, he is assured of the capacity to run the six Reserved Instances when he needs them.

**Reserved Instances and Consolidated Billing**

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing (CB) payer account. Consolidated billing allows you to pay all of your charges using one account, the CB payer account. The amount of hourly usage for each month across all sub-accounts is also aggregated in the CB payer account. This billing is typically useful for companies in which there are different functional teams or groups. For more information on consolidated billing, see *Consolidated Billing* in About AWS Billing and Cost Management.

For Reserved Instances, the amount of usage across all linked accounts is aggregated in the CB payer account, by the hour for each month. Then the normal Reserved Instance logic is applied to calculate the bill.

For example, your account is part of a consolidated billing account, and using your account you purchase Reserved Instances. The upfront cost of the Reserved Instances is paid by the CB payer account, and the discount is spread across the sub-accounts. The allocation of the total cost is determined by the ratio of each sub-account's usage divided by the total usage of the CB payer account. However, the capacity reservation remains with the sub-account that purchased the reservation—in this example, your account. Keep in mind that capacity reservation only applies to the product platform, instance type, and Availability Zone specified in the purchase.

For more information about how the discounts of the Reserved Instance pricing tiers apply to consolidated billing accounts, see *Understanding Reserved Instance Pricing Tiers* (p. 205).

**Reserved Instance Marketplace**

The Reserved Instance Marketplace is an online marketplace that provides AWS customers the flexibility to sell their unused Amazon Elastic Compute Cloud (Amazon EC2) Reserved Instances to other businesses and organizations. Customers can also browse the Reserved Instance Marketplace to find a wide selection of Reserved Instance term lengths and pricing options sold by other AWS customers (listed as 3rd-Party sellers). The Reserved Instance Marketplace gives customers the flexibility to sell the remainder of their Reserved Instances as their needs change. For example, a customer may want to move instances to a new AWS region, change to a new instance type, or sell capacity for projects that end before the term expires. EC2 Instances purchased on the Reserved Instance Marketplace offer the same capacity reservations as Reserved Instances purchased directly from AWS.

**Note**

Some restrictions—such as what is required to become a seller and when you can sell your reserved capacity—apply. For information about restrictions and requirements for Reserved Instances and the Reserved Instance Marketplace, see *Requirements Checklist for Reserved Instances* (p. 266).

For a buyer, there are a few differences between these Reserved Instances and Reserved Instances purchased directly from Amazon Web Services (AWS):

- **Term.** The Reserved Instances that you purchase from third-party sellers on the Reserved Instance Marketplace will have less than a full standard term remaining. Full standard terms for Reserved Instances available from AWS run for one year or three years.
- **Upfront price.** Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees will remain the same as the fees set when the Reserved Instances were originally purchased from AWS.
- **Tiered discounts.** Amazon EC2 Reserved Instances purchased at a reduced cost because a discount tier threshold had been crossed cannot be sold in the Reserved Instance Marketplace. For information about the Reserved Instance pricing tiers, see *Understanding Reserved Instance Pricing Tiers* (p. 205)
As a seller, you can choose to list some or all of your Reserved Instances, and you can choose the upfront price you want to receive. Your Reserved Instances are then listed in the Reserved Instance Marketplace and are available for purchase. You will be charged a service fee of 12 percent of the total upfront price for each Reserved Instance you sell in the Reserved Instance Marketplace. You can use your Reserved Instance until it’s sold. When you sell, you are giving up the capacity reservation and the accompanying discounted fees. This means that you can continue to use your instance after you have sold your capacity reservation. You will just have to pay the On-Demand price for the instance, starting from the time that the reserved capacity on the instance was sold.

**Note**

Only Amazon EC2 Reserved Instances can be sold in the Reserved Instance Marketplace. Other AWS Reserved Instances, such as Amazon Relational Database Service (Amazon RDS) and Amazon ElastiCache Reserved Instances cannot be sold on the Reserved Instance Marketplace.

For information about Reserved Instances, see [Reserved Instances](p. 198).

### Buyer Overview

The Reserved Instance Marketplace is useful if you want to buy Reserved Instances with terms that are different from the terms offered by AWS. You can search the marketplace for Reserved Instances with configurations that address your specific business needs.

**Quick Start: Buying in the Reserved Instance Marketplace Video**

The following video shows you how to buy Reserved Instances in the Reserved Instance Marketplace using the AWS Management Console. [Getting Started Buying Reserved Instances in the Reserved Instance Marketplace](p. 217)

**Requirements**

To purchase Reserved Instances in the Reserved Instance Marketplace, you must have a valid Amazon Web Services (AWS) account. For information on setting up an AWS account, see [Getting Started with Amazon EC2 Linux Instances](p. 24).

If you have purchased Amazon EC2 Reserved Instances in the past, you will find that the process and tools for purchasing Reserved Instances in the Reserved Instance Marketplace are very familiar.

**Steps to buying Reserved Instances**

The steps to purchasing Reserved Instances—whether they are standard AWS Reserved Instances or instances in the Reserved Instance Marketplace—are the same.

1. Specify the details of the Reserved Instance you want to purchase.
2. Select the Reserved Instance you want from the list identified by the Reserved Instance Marketplace based on your specifications.
3. Confirm your choice and purchase.

For more information, see [Purchasing Reserved Instances](p. 217).

### Seller Overview

The Reserved Instance Marketplace will be useful to you if you own Reserved Instances and want to sell the remainder of the term of your reserved capacity, or if your business is looking for Reserved Instances with configurations that are different from the ones you currently own. The marketplace gives you the opportunity to sell your instances to businesses with needs for short-term workloads and they want to purchase Reserved Instances outside the standard one-year and three-year term lengths.

Listing on the Reserved Instance Marketplace provides you the flexibility to move to new Reserved Instance configurations when your business needs change. For example, say you currently own several
three-year, m1.xlarge Reserved Instances in the EU (Ireland) Region. This year, your customer base expanded to Asia, so you need an m1.large Reserved Instance that you can use in the Asia Pacific (Tokyo) Region. You can use the Reserved Instance Marketplace to sell the remainder of the term on some of your m1.xlarge Reserved Instances purchased in the EU (Ireland) Region and purchase capacity in the Asia Pacific (Tokyo) Region.

Note
AWS will charge you a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the marketplace.

Quick Start: Selling in the Reserved Instance Marketplace Video

The following video shows you how to sell Reserved Instances in the Reserved Instance Marketplace using the AWS Management Console. This video includes instructions on registering as a seller and listing your instances. Getting Started Selling Reserved Instances in the Reserved Instance Marketplace

Requirements

- **Register as a seller.** Any US legal entity or non-US legal entity can sell in the Reserved Instance Marketplace by first registering as a seller. For information, see Registering as a Seller (p. 241).
- **Complete the tax registration.** Sellers who have 200 or more transactions or who plan to sell $20,000 or more in Reserved Instances will have to provide additional information about their business for tax reasons. For information, see Tax Information (p. 243).
- **Provide a US bank.** AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see Your Bank (p. 242).

Steps to selling Reserved Instances

After you have registered as a seller and have provided all required information, you are ready to sell your Reserved Instances in the Reserved Instance Marketplace.

1. Select the Reserved Instances you want to sell.
2. Choose the price at which you want your Reserved Instances to sell.
3. List your Reserved Instances.

For more information, see Selling in the Reserved Instance Marketplace (p. 240).

Buying Reserved Instances

You can purchase Amazon EC2 Reserved Instances with one- or three-year terms from Amazon Web Services (AWS) or you can purchase EC2 Reserved Instances from third-party sellers who own EC2 Reserved Instances that they no longer need. Reserved Instances bought from third parties and sold through the Reserved Instance Marketplace work like Reserved Instances purchased from AWS, and the purchase process is the same. The only differences are that Reserved Instances purchased from third parties will have less than a full term remaining, and they can be sold at different upfront prices.

For a buyer, the Reserved Instance Marketplace provides increased selection and flexibility by allowing you to search for Reserved Instances that most closely match your preferred combination of instance type, region, and duration.

It is important to note that once you have purchased a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase. However, you can modify your Reserved Instances and you can sell them if your needs change. For information about modifying your Reserved Instances, see Modifying Your Reserved Instances (p. 230). For information about selling your Reserved Instances in the Reserved Instance Marketplace, see Selling in the Reserved Instance Marketplace (p. 240).

This buyer's guide contains the following sections:

- **How Buying Works (p.215)**—Provides an overview of what you need to get started buying in the Reserved Instance Marketplace.
- **Becoming a Buyer (p. 216)**—Discusses what you need to do to become a buyer in the Reserved Instance Marketplace, the information you have to disclose, and the reasons why certain information is necessary.
- **Purchasing Reserved Instances (p. 217)**—Walks you through the purchase process, which involves tasks that you likely will be repeating if you decide to use the Reserved Instance Marketplace.
- **Reading Your Statement (Invoice) (p. 223)**—Helps you understand your bill.

For general information about the Reserved Instance Marketplace, see Reserved Instance Marketplace (p. 212). For information about selling Reserved Instances in the Reserved Instance Marketplace, see Selling in the Reserved Instance Marketplace (p. 240). For basic information about Reserved Instances, see Reserved Instances (p. 198).

How Buying Works

Before you start using the Reserved Instance Marketplace, you must first create an account with AWS. To make a purchase in the Reserved Instance Marketplace, you specify the details of the Reserved Instances that you want to purchase in the AWS Management Console search wizard. You then are presented with options that match your request. Any Reserved Instance you select must be purchased just as it is listed—that is, you cannot change the term, the instance type, and so on.

After you select Reserved Instances to purchase, AWS will provide you a quote on the total cost of your selections. When you decide to proceed with the purchase, AWS will automatically place a *limit price* on the purchase price, so the total cost of your Reserved Instances will not exceed the amount you were quoted. If the price rises for any reason, AWS will automatically return you to the previous screen and let you know that your purchase did not complete because the price had changed. In addition, if at the time
of purchase, there are offerings similar to your choice but at a lower price, AWS will sell you the offerings at the lower price instead of your higher-priced choice.

The Reserved Instance pricing tier discounts only apply to purchases made from AWS. These discounts do not apply to purchases of third-party Reserved Instances. For example, if you purchase $250,000 worth of Reserved Instances from a third party in the Reserved Instance Marketplace, and then you purchase another set of third-party Reserved Instances that puts your total list price above the first discount pricing tier threshold, you will not get the 10 percent discount associated with that tier. However, if after your purchases from the marketplace cross a discount pricing threshold, you then purchase a Reserved Instance from AWS, your purchase from AWS will be discounted. For more information, see Understanding Reserved Instance Pricing Tiers (p. 205).

You can determine if your Reserved Instance transaction has completed by looking at the Reserved Instances page in the Amazon EC2 console, or the results of the `ec2-describe-reserved-instances` command, or the `DescribeReservedInstances` action. If the purchase is successful, your Reserved Instance will transition from the pending-payment state to the active state.

When you buy Reserved Instances and your payment fails, the console, the `ec2-describe-reserved-instances` command, and the `DescribeReservedInstances` action will display this failed transaction by showing the Reserved Instance that you attempted to purchase to be payment-failed, changing from the previous payment-pending state.

**Becoming a Buyer**

Becoming a buyer is simple and easy. If you already have an Amazon Web Services (AWS) account, you are ready to start purchasing. For more information, see the following sections:

- Understanding the Information a Buyer Discloses (p. 216)
- Purchasing Reserved Instances (p. 217)

If you don't have an AWS account, you first have to sign up and create an account with AWS. For more information, see Getting Started with Amazon EC2 Linux Instances (p. 24). If you are new to Reserved Instances, see Getting Started with Reserved Instances (p. 199).

**Understanding the Information a Buyer Discloses**

Some basic information about the buyer will be shared with the seller. If you are the buyer, your ZIP code and country information will be provided to the seller in the disbursement report. This information will enable sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax). In rare circumstances, AWS might have to provide the seller with your email address, so that the seller can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS will share the legal entity name of the seller on the buyer's purchase invoice. In addition, if you need additional information about the seller for tax or related reasons, you can call AWS Customer Service.

**Next Steps**

After you have signed up with AWS, you can begin buying Reserved Instances in the Reserved Instance Marketplace.

- To find the Reserved Instances that address your specific business needs, see Purchasing Reserved Instances (p. 217).
- To understand your invoice, see Reading Your Statement (Invoice) (p. 223).
- To sell your unused Reserved Instances, see Selling in the Reserved Instance Marketplace (p. 240).
Purchasing Reserved Instances

The procedure for buying Amazon EC2 Reserved Instances from third parties in the Reserved Instance Marketplace is essentially the same as the procedure for purchasing Reserved Instances from Amazon Web Services (AWS). You can purchase Reserved Instances in the Reserved Instance Marketplace using the AWS Management Console, the Amazon EC2 command line interface (CLI) tools, or the Amazon EC2 API.

**AWS Management Console**

To find and purchase a Reserved Instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click **Reserved Instances** in the **Navigation** pane.
3. In the **Reserved Instances** page, click **Purchase Reserved Instances**.
4. In the **Purchase Reserved Instances** page, specify the details of the Reserved Instances you want to purchase (use familiar filters like **Platform**, **Instance Type**, **Availability Zone**, **Term**, and **Tenancy**), and click **Search**.

The **Purchase Reserved Instances** wizard will display a list of Reserved Instances that meet your search criteria.

5. Select the Reserved Instances that you want, enter the quantity that you want to purchase, and click **Add to Cart**. You can continue to select more Reserved Instances and add them to your cart.

The **Seller** column indicates whether the seller is a **3rd Party** seller or **AWS**. Notice that the **Term** column gives you non-standard terms if the seller is a third-party seller. At the bottom of the page, the **Purchase Reserved Instances** wizard keeps a running tally of the total in your cart.
6. Click **View Cart** to see a summary of the Reserved Instances that you have selected.

If you want to add more Reserved Instances to your cart, click **Add More To Cart**. If you want to remove an item from your cart, click **Delete**.

Or, click **Cancel** if you want to start over or search for a different set of Reserved Instances.

7. Click **Purchase** when you have all the Reserved Instances you want to purchase, and you want to check out.

   **Note**
   
   If at the time of purchase, there are offerings similar to your choice but with a lower price, AWS will sell you the offerings at the lower price.
Your purchase is complete.

8. To verify your order, go to the **Reserved Instances** page in the EC2 console.

The **Reserved Instances** page displays a list of Reserved Instances that belong to your account, including the new Reserved Instance that you just purchased.

You can use your Reserved Instance any time after your purchase is complete. This means that the **State** of your Reserved Instance has changed from **payment-pending** to **active**. To use your Reserved Instance, you launch an instance in the same way you launch an On-Demand instance. Just make sure to specify the same criteria that you specified for your Reserved Instance. AWS will automatically charge you the lower hourly rate. You do not have to restart your instance.

**Amazon EC2 CLI**

**To find and purchase a Reserved Instance**

1. **Use** `ec2-describe-reserved-instances-offerings` **to get a list of Reserved Instance offerings that match your specifications. In this example, we’ll check to see what m1.small, Linux/UNIX Reserved Instances are available in the sa-east-1b Availability Zone.**

   ```shell
   ec2-describe-reserved-instances-offerings --t m1.small --z sa-east-1b --d Linux/UNIX --headers
   ```

   Amazon EC2 returns output similar to the following example:
The preceding output shows a part of the overall offerings that are available.

**Tip**

You can filter this list to return only certain types of Reserved Instances offerings of interest to you. For more information about how to filter the results, see `ec2-describe-reserved-instances-offerings` in the *Amazon Elastic Compute Cloud Command Line Reference*.

2. From the list of available Reserved Instances, purchase the Reserved Instances that meet your requirements. To purchase a Reserved Instance, use the following command.

```
PROMPT> ec2-purchase-reserved-instances-offering --offering offering --instance-count count
```

Amazon EC2 returns output similar to the following:

```
PURCHASE  af9f760e-c1c1-449b-8128-1342dexample  438012d3-80c7-42c6-9396-a209cexample
```

The response includes the offering ID and a reservation ID.

3. Write down and save the reservation ID for future reference.

4. Verify the purchase.

```
PROMPT> ec2-describe-reserved-instances
```
Amazon EC2 returns output similar to the following:

<table>
<thead>
<tr>
<th>RESERVEDINSTANCE</th>
<th>af9f760e-c1c1-449b-8128-1342dexample</th>
<th>sa-east-1b</th>
</tr>

<td>227.5</td>
</tr>
<tr>
<td></td>
<td>0.03</td>
<td>Linux/UNIX</td>
</tr>
<tr>

<td>Active</td>
<td></td>
</tr>
</tbody>
</table>

You can run your Reserved Instance any time after your purchase is complete. To run your Reserved Instance, you launch it in the same way you launch an On-Demand instance. Make sure to specify the same criteria that you specified for your Reserved Instance. AWS will automatically charge you the lower hourly rate.

**Amazon EC2 API**

**To find and purchase a Reserved Instance**

1. Use `DescribeReservedInstancesOfferings` to get a list of Reserved Instance offerings that match your specifications. In this example, we'll check to see the available Linux/UNIX, Heavy Utilization Reserved Instances.

   ```
   https://ec2.amazonaws.com/?Action=DescribeReservedInstancesOfferings

You can run your Reserved Instance any time after your purchase is complete. To run your Reserved Instance, you launch it in the same way you launch an On-Demand EC2 instance. Make sure to specify the same criteria that you specified for your Reserved Instance. AWS will automatically charge you the lower hourly rate.

**Reading Your Statement (Invoice)**

**Account Activity**

You can find out about the charges and fees to your account by viewing your **Account Activity** page in the AWS Management Console. You can access it by clicking the drop-down arrow beside your account name.
The Account Activity page will show all charges against your account—such as upfront and one-time fees and recurring charges. You can get both a summary of all your charges and a detailed list of your charges.

The upfront charges from your purchase of third-party Reserved Instances in the Reserved Instance Marketplace will be listed in the AWS Marketplace Charges section, with the name of the seller displayed beside it. However, all recurring or usage charges for these Reserved Instances will be listed in the AWS Service Charges section.

You can view the charges online, and you can also download a PDF rendering of the charge information.
The **Detail** section contains information about the Reserved Instance—such as the Availability Zone, instance type, cost, and number of instances. It also includes the name of the seller of the Reserved Instances that you purchased.

### Obtaining Information About Your Reserved Instances

Information about your Reserved Instances, such as state, instance type, Availability Zone, and term is useful when you decide to use the capacity reservation. You can check information about the Reserved Instances that are available to your account using any of the Amazon EC2 tools that you've used either for purchasing or selling.

### Reserved Instance States

Reserved Instances can be in one of the following states:

- **Active**—The Reserved Instance is available for use.
- **Payment-Pending**—Amazon Web Services (AWS) is processing your payment for the Reserved Instance. You will be able to use the Reserved Instance when the state becomes Active.
- **Retired**—The Reserved Instance has been terminated. It could have reached this state because of any of the following reasons:
  - AWS did not receive your payment. For example, the credit card transaction did not go through.
  - The Reserved Instance term expired.
  - The Reserved Instance was canceled.
Status information displayed in the State column in the Reserved Instance page is different from the status information displayed in the Listing State in the My Listings tab. The State column displays status of the Reserved Instance; the Listing State displays status of the Reserved Instance Listing. The My Listings tab shows information only if you are a seller in the Reserved Instance Marketplace. For more information, see Reserved Instance Listing States (p. 265).

AWS Management Console

To view your listing

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Reserved Instances in the Navigation pane.

   The Reserved Instances page displays a list of your account's instances.

3. Select a Reserved Instance. The Details tab displays details about the instance you selected.

4. If you are a seller in the Reserved Instance Marketplace and you want information about your Reserved Instance listing, click the My Listings tab. You will see details about the Reserved Instance listing you selected.

Modifying Your Reserved Instances

When your computing needs change, you can modify your Reserved Instances and continue to benefit from your capacity reservation. You can move your Reserved Instances between Availability Zones within the same region, and you can change the network platform between EC2-Classic and EC2-VPC. In addition, starting with Amazon EC2 API version 2013-10-01, you can change the instance type of your reservation to a larger or smaller instance type in the same family (e.g., the M1 instance family) if capacity is available and if your reservation is for the Linux/UNIX product platform (currently the only platform that can be modified).

Modification does not change the remaining term of your Reserved Instances. Their end dates remain the same. There is no fee for modifying your Reserved Instances, and you do not receive any new bills or invoices.

Instances covered by Reserved Instances continue to run even if you modify your reservation. However, after modification, the pricing benefit of the Reserved Instances starts applying to instances that match the new parameters of your Reserved Instances. You are charged at the On-Demand rate for the EC2 instances no longer receiving the benefits of the modified Reserved Instances, unless your account has other applicable reservations, in which case you will be charged at the rate of these other Reserved Instances.

Modification does not affect how you use, purchase, or sell Reserved Instances. When you purchase Reserved Instances, you still need to specify the product platform, instance type, network platform, tenancy, term length, offering type, and Availability Zone.

You can view the status of your request in the AWS Management Console, or when you call the `DescribeReservedInstancesModifications` API action or `ec2-describe-reserved-instances-modifications` CLI command.

This section discusses the modification process:

- **Understanding the Modification Process** (p. 230)—What happens when I submit a modification request?
- **Determining the Status of Your Modification** (p. 232)—How do I track my modification requests?
- **Requirements for Modification** (p. 233)—Which Reserved Instances can I modify?
- **Changing the Instance Type of Your Reservations** (p. 233)—When can I change the instance size of my Reserved Instances?
- **Submitting Modification Requests** (p. 236)—How do I modify my Reserved Instances?

**Understanding the Modification Process**

You can modify your Reserved Instances in one or more of the following ways:

- **Move them between Availability Zones within the same region.**
  
  If you modify the Availability Zone of your Reserved Instances, the capacity reservation and pricing benefit stop applying to instance usage in the original zone, and start applying to usage in the new Availability Zone.
  
  - Change the network platform of the Reserved Instances between EC2-VPC and EC2-Classic.
If you modify the network platform of your Reserved Instances, the capacity reservation stops applying to instance usage with the original network platform, and starts applying to usage with the new network platform. However, the pricing benefit continues to apply to both EC2-Classic and EC2-VPC instance usage matching the remaining Reserved Instances parameters.

- Upgrade or downgrade the instance type of your Reserved Instances within the same instance family (e.g., the M1 instance family).

If you modify the instance type of your Reserved Instances, you must ensure that the instance family of your reservation has a larger or smaller instance type available and that you have enough applicable Reserved Instances to make the change.

You can modify your whole reservation or a subset of your reservation. When you modify a subset of your reservation, Amazon EC2 splits your original Reserved Instances into two or more new Reserved Instances. For example, if you have Reserved Instances for 10 instances in us-east-1a, and decide to move 5 instances to us-east-1b, the modification request results in two new Reserved Instances—one for 5 instances in us-east-1a (the original zone), and the other for 5 instances in us-east-1b.

Amazon EC2 fulfills your modification request as soon as possible, depending on available capacity. Until your modification request completes, the capacity reservation and pricing benefit associated with your Reserved Instances continue to be based on the original parameters of your reservation.

**Note**
You cannot cancel or change a pending modification request after you submit it. While your modification is being processed, the status of the Reserved Instances that you’re modifying is **active (pending modification)**. After the modification has completed successfully, you can submit another modification request to roll back any changes you made.

If your Reserved Instances modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit of the Reserved Instances is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your Reserved Instances at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. (You can get the **effective date** of the modified Reserved Instances by using the DescribeReservedInstances API action or the `ec2-describe-reserved-instances` CLI command.)

- The end date of the modified Reserved Instances is the same as the original end date of the reservation. If you successfully modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month Reserved Instance with the same end date as the original Reserved Instances.

For example, in the following table, Modification #1 shows RI af9f760... was modified successfully and retired on 2013-08-30 16:00 UTC-7 and a new RI 46a408c... was created as a result of the modification on the same date-time that RI af9f760... was retired. Modification #2 shows RI 46a408c... was modified successfully and retired on 2013-09-03 14:00 UTC-7 and a new RI b847la9... was created as a result of the modification on the same date-time that RI 46a408c... was retired.
• The original reservation is retired. Its end date is the start date of the new reservation, and the end
date of the new reservation is the same as the end date of the original Reserved Instance when it was
active.
• The modified Reserved Instances shows $0 fixed price and not the fixed price of the original Reserved
Instances.

Note
The fixed price of the modified reservation does not affect the discount tier calculations applied
to your account, which are based on the fixed price of the original reservation.

If your modification request fails:
• Your Reserved Instances maintain the original properties that they had prior to your request.
• Your Reserved Instances are available for another modification request.

You can determine the status of your request by looking at the state of the Reserved Instances that you
are modifying. For information, see Determining the Status of Your Modification (p. 232).

Determining the Status of Your Modification

The state of your modification request is displayed in the State field in the AWS Management Console.
You can also use the DescribeReservedInstancesModifications API action to get detailed
information about your modification request: The state returned shows your request as in-progress,
fulfilled, or failed.

You can only modify your Reserved Instances if they are active. You are not able to modify Reserved
Instances that are in any other state. You also cannot modify your Reserved Instances if they are listed
in the Reserved Instance Marketplace. For more information, see Requirements for Modification (p. 233).
If your Reserved Instances are not in the active state or cannot be modified, the Modify Reserved
Instances button in the AWS Management Console is not enabled. If you use the API to modify Reserved
Instances that are not active, you will get an error.

In cases when you select Reserved Instances whose Availability Zone and network platform can be
modified, but whose instance types cannot be changed, the Modify Reserved Instances button is enabled
and you can proceed to the Modify Reserved Instances page. However, you do not have the option to
modify the instance type. For more information, see Changing the Instance Type of Your
Reservations (p. 233).

Modification States

The modification request is being processed. While the modification request is being processed, the
status of the Reserved Instances being modified show as active (pending modification). The Reserved
Instances are in this state only for a short period. The state reverts to active or becomes retired, depending
on the success of the modification. (If you use the DescribeReservedInstancesModifications API
action, the status of your modification request should show processing.)

The modification succeeded. If the modification is successful, the Reserved Instances being modified are retired, and new Reserved Instances are created with the modification configuration that you requested. The status of these new Reserved Instances is active. (If you use the
DescribeReservedInstancesModifications API action, the status of your modification request should show fulfilled.)

Note
For the brief period that the new Reserved Instances are being activated, the original Reserved
Instances show as retired (pending modification).
The modification failed. If the modification did not complete, the Reserved Instances being modified return to the active state. (If you use the DescribeReservedInstancesModifications API action, the status of your modification request should show failed.) For information about why some Reserved Instances cannot be modified, see Requirements for Modification (p. 233).

Requirements for Modification

Amazon EC2 processes your modification request if the following conditions are met:

- We have sufficient Reserved Instances capacity for your target configuration.
- The Reserved Instances you are modifying are active.
- The Reserved Instances are not pending another modification request.

You may modify your Reserved Instances as frequently as you like. However, you cannot submit a modification request for Reserved Instances that are still pending a previous modification request; that is, if the previous modification request is in the active (pending modification) state. For information about modification states, see Determining the Status of Your Modification (p. 232).
- The Reserved Instances are not listed in the Reserved Instance Marketplace.

To modify Reserved Instances that are listed in the Reserved Instance Marketplace, cancel the listing, modify the Reserved Instances, and then list them again.

In addition, you cannot modify a Reserved Instance Marketplace offering before or at the same time that you purchase it. However, you can submit a modification request after you purchase a Marketplace offering. For more information, see Reserved Instance Marketplace (p. 212).
- Only the following attributes are being modified: Availability Zone in the same Region, instance type in the same instance family (e.g., the M1 instance family), and network platform.
- When combining Reserved Instances, the end dates of the Reserved Instances must have the same hour digits in 24-hour format, but they do not need to have the same minutes or seconds. This means you can combine Reserved Instances if they end on the same day at 13:01 and 13:59, but not if they end at 12:59 and 13:01.
- When modifying the instance type attribute
  - The Reserved Instances you are modifying must be for the Amazon Linux/UNIX product platform (currently the only product platform for which instance type modifications are allowed).
  - The new instance type of the Reserved Instances must be in the same instance family (e.g., the M1 instance family) as the original reservation.
  - If you are upgrading the instance type of your Reserved Instances, the normalized instance count for the target Reserved Instance configuration must equal the normalized instance count of the original reservation.

If you select multiple Reserved Instances for modification and one or more of these Reserved Instances are for a product platform that does not allow instance type modification, the Modify Reserved Instances page will not show the option of changing the instance type for any of the selected Reserved Instances. For information about modifying instance types, see Changing the Instance Type of Your Reservations (p. 233).
- The attributes for the target Reserved Instance configuration must result in a unique combination of Availability Zone, instance type, and network platform.

For information about how to modify Reserved Instances, see Submitting Modification Requests (p. 236).

Changing the Instance Type of Your Reservations

Under certain conditions, you can adjust the instance type of your Reserved Instances. If you have capacity reservations for Amazon Linux/UNIX in instance families with multiple instance sizes, you can request to modify your Reserved Instances to include different instance types within the same family. Your request
proceeds successfully if the capacity exists and the modification does not change the instance size footprint of your Reserved Instances.

For example, you can divide a reservation for one m1.large instance into four m1.small instances, or you can combine a reservation for four m1.small instances into one m1.large instance. In either case, the instance size footprint of the reservation does not change. On the other hand, you cannot change your reservation for two m1.small instances into one m1.large instance because the existing instance size footprint of your current reservation is smaller than the proposed reservation.

Instance size footprints are determined by the normalization factor of the instance type and the number of instances in the reservation. This section discusses the two ways you can change the instance type of your Reserved Instances, and how you use the instance type's normalization factor to figure out what instance type modifications you can make.

- Understanding the Instance Normalization Factor (p. 234)
- Upgrading Your Instance Type (p. 235)
- Downgrading Your Instance Type (p. 235)

**Exceptions**

The following instance type sizes cannot be modified because there are no other sizes in their families.

- t1.micro
- cc1.4xlarge
- cc2.8xlarge
- cg1.8xlarge
- cr1.8xlarge
- hi1.4xlarge
- hs1.8xlarge
- g2.2xlarge

When you try to modify Reserved Instances that have instance types or product platforms that cannot be modified, you can proceed to the Modify Reserved Instances page, but the Amazon EC2 console limits the modification options to Network and Availability Zone.

Keep in mind that instance type modifications are allowed only if other Reserved Instances specification details match—such as region, utilization type, tenancy, product, end date and hour—and capacity is available. In addition, such modifications do not change the discounted hourly usage fee that you are billed, or the end date of your reservation.

**Understanding the Instance Normalization Factor**

Each Reserved Instance has an instance size footprint. When you modify the instance type of Reserved Instances, the footprint is maintained even if the instance type is downsized or upsized. A modification request is not processed if the footprint of the target configuration does not match the size of the original configuration.

The size of an instance type's footprint can be calculated by using its normalization factor, which is based on the type's size within the instance family (e.g., the M1 instance family). Normalization factors are only meaningful within the same instance family; instance types cannot be modified from one family to another.

The following table illustrates the normalization factor that applies within an instance family. For example, an m1.small instance has a normalization factor of 1, an m1.medium instance has a factor of 2, and an m1.large instance has a factor of 4.
<table>
<thead>
<tr>
<th>Instance Size</th>
<th>Normalization Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>small</td>
<td>1</td>
</tr>
<tr>
<td>medium</td>
<td>2</td>
</tr>
<tr>
<td>large</td>
<td>4</td>
</tr>
<tr>
<td>xlarge</td>
<td>8</td>
</tr>
<tr>
<td>2xlarge</td>
<td>16</td>
</tr>
<tr>
<td>4xlarge</td>
<td>32</td>
</tr>
<tr>
<td>8xlarge</td>
<td>64</td>
</tr>
</tbody>
</table>

Each Reserved Instance has a total number of normalized instance units, which is equal to the instance count multiplied by the normalization factor of the instance type. For example, an m1.medium has a normalization factor of 2 so a Reserved Instance for four m1.medium instances is worth eight normalized instance units. You arrive at the value this way:

\[4 \text{ [count]} \times 2 \text{ [normalization factor]}\]

You can allocate your Reserved Instances into different instance sizes across the same instance family (e.g., the M1 instance family) as long as the total normalized instance units of your Reserved Instances remain the same. If you have Reserved Instances for four m1.medium instances, you can turn it into a reservation for eight m1.small instances (m1.small instances have a normalization factor of 1, thus 8 x 1). The resulting Reserved Instances would have the same normalized instance units or instance size footprint.

**Upgrading Your Instance Type**

You can consolidate a reservation of multiple smaller instance types that belong to one instance family (e.g., the M1 instance family) into a reservation for a larger instance type in the same family. To upgrade or upsize your reservation, you must have enough of the smaller instance types in the same reservation to consolidate into larger instance types, and your reservation’s overall instance size footprint does not change.

For example, you can convert four m1.small instances, which is equivalent to four normalized instance units (4 x 1), into one m1.large instance, which is also equivalent to four normalized units (1 x 4). However, you cannot convert a reservation for a single m1.small instance (1 x 1) into a reservation for an m1.large instance (1 x 4). The two reservations are not equal.

Instance families that have multiple instance sizes, and are not listed in the Exceptions (p. 234) list, can be changed or upgraded to larger instance type sizes.

**Downgrading Your Instance Type**

You can change Reserved Instances for a large instance type to several Reserved Instances of smaller instance types of the same family (e.g., the M1 instance family). When you downgrade or downsize your Reserved Instances, you are actually dividing a large reservation into multiple smaller reservations. Just as with up sizing instance types, you can downsize successfully only if your reservation’s overall instance size footprint does not change.

For example, a reservation for two m1.large instances equals eight normalized instance units (2 x 4). Assuming there is capacity, they can be converted to a Reserved Instance for four m1.medium instances, which is also equivalent to eight normalized instance units (4 x 2).
Instance families that have multiple instance sizes, and are not listed in the Exceptions (p. 234) list, can be changed or downgraded to smaller instance type sizes.

For information about Amazon EC2 instance types, see Instance Types (p. 97). For information about Reserved Instances modification requests, see Submitting Modification Requests (p. 236).

**Submitting Modification Requests**

You can use the AWS Management Console to modify your Reserved Instances in the following ways:

- Move all or some of your capacity reservation to another Availability Zone in the same region.
- Change the network platform of all or some of your Reserved Instances from EC2-Classic to EC2-VPC, or vice versa.
- Upgrade or downgrade all or some of the instance types of your Reserved Instances within the same instance family (e.g., the M1 instance family) as long as there is capacity and the change maintains the footprint of your capacity reservation.

You can also complete these modification tasks programmatically by using the AWS CLI (modify-reserved-instances), Amazon EC2 CLI (ec2-modify-reserved-instances), Amazon EC2 API (ModifyReservedInstances), and the AWS SDK for Java.

For information about programming tools you can use to modify Reserved Instances, see Tools for Working with Reserved Instances (p. 202).

**Using the Modifying Reserved Instances Page**

In this section, you will learn how to use the Modify Reserved Instances page in the Amazon EC2 Console to make modifications. We will also discuss the following:

- Count and Units Values (p. 236)
- Messages About Your Modification Requests (p. 239)

**Count and Units Values**

The Modify Reserved Instances page in the EC2 console keeps track of the total count and units of the Reserved Instances that you have allocated for the target (or new) configurations versus the total number of Reserved Instances available for you to modify. Count is the literal number of instances for the current instance type. Units represent the total instance size of your reservation relative to its instance family (e.g., the M1 instance family). The value of the units equals the count multiplied by the normalization factor of the instance type. For information about the instance normalization factor, see Understanding the Instance Normalization Factor (p. 234).

Each target configuration row for your Reserved Instances has a count and units value. The allocated total is displayed in red if you have specified either more or fewer Reserved Instances than are available for modification. You cannot click Continue if the total units you have specified for your target configurations do not equal the total number of units of Reserved Instances available to modify. The units displayed will change to green after you have specified changes for all the Reserved Instances that were available for modification.

**To modify your Reserved Instances**

1. On the Reserved Instances page, select one or more Reserved Instances to modify, and click Modify Reserved Instances.
The Modify Reserved Instances page opens with the Reserved Instances you selected and their current configuration.

2. Decide how to modify your Reserved Instances. For this example, you want to modify your Reserved Instances so that 2 are not changed, 2 are moved to another Availability Zone, 2 are converted from EC2-Classic to EC2-VPC, and 2 are upgraded from m1.medium to m1.large instance type. Keep in mind that to upgrade, you will need 2 m1.medium instances for every 1 m1.large instance.

The following table illustrates the changes that you want to implement:

<table>
<thead>
<tr>
<th>Modification</th>
<th>Network</th>
<th>Availability Zone</th>
<th>Instance Type</th>
<th>Pre-Change Count</th>
<th>Post-Change Count</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

3. To keep the original configuration (no change) for two Reserved Instances, type 2 for Count, Network, Availability Zone, and Instance Type stay the same. Units automatically updates to 4/20.

Use the Add button to add a row so that each change you want to make to your Reserved Instances is displayed in a separate row.
4. To change the Availability Zone, click Add and select `us-east-1b` in the Availability Zone list. For Count, type 2, Network and Instance Type stay the same. Units automatically updates to 8/20.

5. To change the network platform, first click Add. Then select EC2-VPC in the Network list. For Count, type 2. The Availability Zone and Instance Type stay the same. Units automatically updates to 12/20.

6. To change the instance type, click Add and select `m1.large` in the Instance Type list, and, for Count, type 2. The Availability Zone and Network stay the same. Units automatically updates to 20/20.

If you want to change an instance type, be sure that it can be converted to a larger or smaller set of instance types. For more information about changing instance types, see Changing the Instance Type of Your Reservations (p. 233).

In our example, you are upgrading from an m1.medium to an m1.large instance type, which has a larger footprint. The normalization factor for m1.large instance types is 4; to get one m1.large instance type you'll need 4 m1.small or 2 m1.medium instance types. Therefore, the remaining 4 m1.medium instance types, which have a normalized value of 8, can be upgraded to 2 m1.large instance types, which also have a normalized value of 8. Units will be 20/20 in green, which means that you have specified changes for all the Reserved Instances that were available for modification in this exercise and you can proceed with your modification request.

For more information about the instance normalization factor, see Understanding the Instance Normalization Factor (p. 234).

7. If you want to delete a configuration that you specified, such as the instance upgrade, click X for that row.

**Note**
If the Modify Reserved Instances page contains only one row for configuration changes, you cannot delete that row.
8. To confirm your modification choices when you finish specifying your target configurations, click **Submit Modifications**. Amazon EC2 checks your modification request. If the configuration settings you requested were unique, the instance count that you specified matches the total number of Reserved Instances available for you to modify, you will be informed that Amazon EC2 is processing your request.

**Note**
At this point, Amazon EC2 has only determined that the parameters of your modification request are valid, and Amazon EC2 can now process the request. Only during the processing of the modification request, after you get this screen, is the capacity check made. Your modification request can still fail, but at a later point, due to capacity not available.

**Messages About Your Modification Requests**

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for resubmitting another modification request.

- Not all selected Reserved Instances can be processed for modification.

In the following message, Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the **Reserved Instances** page in the EC2 console and check the information details about these capacity reservations.

- Error in processing your modification request.

You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of Reserved Instances you are modifying, you can get different versions of the message.

In these messages, Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform—for one or more subsets of the Reserved Instances you are modifying. Try submitting these modification requests again, but ensure that instance details of the Reserved Instances match, and that the target configurations for all subsets of the Reserved Instances being modified are unique.
What do you want to do next?

• Obtaining Information About Your Reserved Instances (p. 225)
• Buying Reserved Instances (p. 215)
• Selling in the Reserved Instance Marketplace (p. 240)

Selling in the Reserved Instance Marketplace

The Reserved Instance Marketplace gives you the flexibility to sell the remainder of your Reserved Instances as your needs change—for example, if you want to move instances to a different Amazon Web Services (AWS) region, change to another instance type, or sell capacity for projects that end before the Reserved Instance term expires. (Some restrictions—such as what is required to become a seller and when you can sell your reserved capacity apply. For information about restrictions and requirements for Reserved Instances and the Reserved Instance Marketplace, see Requirements Checklist for Reserved Instances (p. 266).)

As soon as you list your Reserved Instances, they will be included in a list that other AWS customers can view. AWS groups Reserved Instances based on the type of instance being listed, the duration of the term remaining, and the hourly price. This grouping makes it easier for buyers to find the Reserved Instances they want to purchase. From the list, customers choose to purchase the instance that best matches their criteria and decide on the best tradeoff between quoted upfront price and hourly price.

To fulfill a buyer’s request, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping; then it sells the Reserved Instance with the next lowest price, until the buyer’s entire purchase order is fulfilled. AWS processes the transaction and transfers ownership of the Reserved Instance to the buyer. Sellers will receive a cash disbursement for their Reserved Instances through a wire transfer directly into their bank account.

When you sell in the Reserved Instance Marketplace, the buyer’s ZIP code and country information will be provided to you through a disbursement report. With this information, you will be able to calculate any necessary tax you need to remit to the government. Your business name (as the seller) will also be provided on the purchase invoice of the buyer. AWS charges an administrative fee (12 percent of the total upfront price) for selling in the Reserved Instance Marketplace. For more information, see Reserved Instance Marketplace in the Amazon EC2 Reserved Instances product page.

You retain control of your Reserved Instance until it’s sold. When you sell, what you are giving up is the capacity reservation and the discounted recurring fees. You can continue to use your instance after you have sold the reserved capacity, but AWS will now charge you the On-Demand price. The On-Demand price will start from the time that your Reserved Instance was sold. Thus, if you don't want to be charged On-Demand prices for instances that you use, purchase more reserved capacity or terminate your instances when your capacity reservation is sold (or expires).

This topic walks you through the steps to selling in the Reserved Instance Marketplace:

• Registering as a Seller (p. 241)—Register as a seller and specify a bank that has a US address. If you plan on 200 or more transactions or if you plan to sell $20,000 or more worth of Reserved Instances over the course of a year, you also have to provide tax information.
• Selling Your Reserved Instances (p. 245)—List an active Reserved Instance that has more than one month left in its term. You also must own the Reserved Instance for longer than a month.
• After Your Reserved Instance Is Sold (p. 264)—Find out when your Reserved Instance is sold, and how you get paid.
• Quick Start: Selling in the Reserved Instance Marketplace Video (p. 214)—Pick up the information you need to quickly get started selling in the Reserved Instance Marketplace.
For information about buying Reserved Instances in the Reserved Instance Marketplace, see Buying Reserved Instances (p. 215). For basic information about Reserved Instances, see Reserved Instances (p. 198).

**Important Notes About Selling in the Reserved Instance Marketplace**

- To become a seller in the Reserved Instance Marketplace, you must register as a seller, and specify a bank that has a US address. For information, see Registering as a Seller (p. 241).
- Reserved Instances can be sold after they have been active for at least 30 days and when AWS has received the upfront payment.
- You can sell up to $50,000 in Reserved Instances per year. If you need to sell more Reserved Instances, complete the Request to Raise Sales Limit on Amazon EC2 Reserved Instances form.
- Amazon EC2 Reserved Instances purchased at a reduced cost resulting from tiered discount cannot be sold in the Reserved Instance Marketplace. For more information about discount pricing tiers, see Understanding Reserved Instance Pricing Tiers (p. 205).

For a checklist that summarizes requirements for working with Reserved Instances and the Reserved Instance Marketplace, see Requirements Checklist for Reserved Instances (p. 266).

**Registering as a Seller**

**Topics**

- Your Bank (p. 242)
- Tax Information (p. 243)
- Seller Registration Confirmation (p. 244)
- Sharing Information with the Buyer (p. 244)
- Next Steps (p. 244)

To be able to sell in the Reserved Instance Marketplace, your first task is to register as a seller.

If you haven't created an AWS account yet, you need to do this first before you register for Reserved Instance Marketplace. Complete the instructions described in Getting Started with Amazon EC2 Linux Instances (p. 24), which provides information about creating your Amazon EC2 account and credentials.

You can access the registration process through the Reserved Instance Marketplace Seller Registration web page. If you try to create a listing and you have not registered, AWS will direct you to this seller registration page.
Registering means providing the name of your business, information about your bank, and your business's tax identification number. Usually, you only have to provide your information once. However, you can update personal and banking information through the Reserved Instance Marketplace Seller Registration web page. Log in to AWS using the account you used when you first registered and the page will send you directly to the personal and banking information pages.

Your Bank

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address.

On the Manage Bank Account page, provide the following information about the bank through which you will receive payment:

- Bank account holder name
- Routing number
- Account number
- Bank account type

Note

If you are using a corporate bank account, you will be prompted to send via fax (1-206-765-3424) the information about the bank account.
You can change the default bank account through which you receive disbursements. Just go to the Reserved Instance Marketplace Seller Registration web page using the account you used when you first registered and the page will send you directly to the personal and banking information pages.

After you have completed the registration, AWS verifies your bank account and sets it as the default bank. You will not be able to receive disbursements until AWS has verified your account with the bank. Verification with the bank can take up to two weeks, so if your account is a new one, you will not get the disbursement as a result of a sale for up to two weeks. For an established account, it will usually take about two days for disbursements to complete.

**Tax Information**

Your sale of Reserved Instances on the Reserved Instance Marketplace might be subject to a transactional tax, such as sales tax or value-added tax. You should check with your business’s tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you have the option of completing a tax interview. We encourage you to complete this process if any of the following apply:

- You want AWS to generate a Form 1099-K.
- You anticipate having either 200 or more transactions or $20,000 or more in sales of Reserved Instances in a calendar year. A transaction can involve one or more Reserved Instances. If you choose to skip this step during registration, and later you reach transaction 199, you will get a message saying, “You have reached the transaction limit for pre-tax. Please complete the tax interview at http://portal.aws.amazon.com/ec2/ri/seller_registration?action=taxInterview.”
- You are a non-US seller. In this case, you must electronically complete Form W-8BEN.

If you complete the tax interview, the tax information you enter will differ depending on whether your business is a US or non-US legal entity. If you are a US seller, you must provide AWS with your tax identification number along with your business contact information.
After you complete the tax registration process, AWS will file Form 1099-K, and you will receive a copy of it through the US mail on or before January 31 in the year after the year that your tax account reaches the threshold levels.

As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, please contact your tax, legal, or other professional advisor.
- In order to fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

For more information about IRS requirements and the Form 1099-K, go to the IRS website.

**Seller Registration Confirmation**

After we receive your completed seller registration, you will get an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

**Sharing Information with the Buyer**

When you sell your Reserved Instances in the Reserved Instance Marketplace, AWS will share your company's legal name on the buyer's statement to comply with US regulations. In addition, if the buyer calls AWS customer service because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS may need to provide the buyer with your email address so that the buyer can contact you directly.

For similar reasons, the buyer's ZIP code and country information will be provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, contact AWS Customer Support.

**Next Steps**

After you have successfully registered as a seller in the Reserved Instance Marketplace, you can begin selling your Reserved Instances. Selling in the Reserved Instance Marketplace requires the following steps:

1. Deciding which Reserved Instances you want to sell.
Identify the active Reserved Instances that you want to sell and select the upfront price at which you want to sell them. For more information, see Pricing Your Reserved Instances (p. 246).

2. Listing your Reserved Instances.

Include your Reserved Instances in the Reserved Instance Marketplace listings. For more information, see Listing Your Reserved Instance (p. 246).

3. Viewing your listings.

You can monitor your Reserved Instances and view your listings. For more information, see Obtaining Information About Your Reserved Instances (p. 225).

4. Canceling and changing your listings.

You can change your listings by first canceling and then relisting. For more information, see Canceling and Changing Your Listings (p. 255).

For information about selling your Reserved Instances, see Selling Your Reserved Instances (p. 245).

Selling Your Reserved Instances

Topics

• Pricing Your Reserved Instances (p. 246)
• Listing Your Reserved Instance (p. 246)
• Canceling and Changing Your Listings (p. 255)

This section walks you through how to list and sell your Reserved Instances in the Reserved Instance Marketplace. If you haven't registered as a seller yet, you must do so first. For information, see Selling Your Reserved Instances (p. 245).

As a registered seller, you can choose to sell one or more of your Reserved Instances, and you can choose to sell all of them in one listing. In addition, you can list any type of Reserved Instance—including any configuration of instance type, platform, region, and Availability Zone—as long as the following requirements are met:

• You have already paid the upfront cost for the Reserved Instance you are listing.

  This means that you can list your Reserved Instance when it is in the Active state. However, keep in mind that a Reserved Instance can be in the Active state before AWS actually receives your payment. If this is the case, the Reserved Instance Marketplace will not allow you to list your Reserved Instance until the payment for the upfront fee is collected.

• You have owned the Reserved Instance for at least a month.

• There is at least a month remaining in the term of the Reserved Instance you are listing.

  You can list the remainder of the Reserved Instance term rounded down to the nearest month. For example, if you have 9 months and 13 days remaining on your Reserved Instance, you can list 9 months for your Reserved Instance.

• The Reserved Instance you are selling is not a discounted or private Reserved Instance. You cannot list these types of Reserved Instances in the Reserved Instance Marketplace.

For a checklist that summarizes requirements for working with Reserved Instances and the Reserved Instance Marketplace, see Requirements Checklist for Reserved Instances (p. 266).

To get details about your existing Reserved Instances, you can use any of the following tools:

• The Reserved Instances page in the EC2 console of the AWS Management Console (p. 202).
• The `ec2-describe-reserved-instances` CLI command.
• The `DescribeReservedInstances` API action.

For more information about Reserved Instances, see Reserved Instances (p. 198).

**Pricing Your Reserved Instances**

When you're a seller on the Reserved Instance Marketplace, the upfront fee is the only fee that you can specify for the Reserved Instance. The upfront fee is the one-time fee that the buyer pays when the buyer purchases a Reserved Instance. The seller cannot specify the usage fee or the recurring fee. The buyer of your Reserved Instance will be paying the same usage or recurring fees that were set when the Reserved Instances were originally purchased. This usage fee applies to Light Utilization and Medium Utilization Reserved Instances, and the fee differs depending on which Reserved Instance offering you're using. The recurring fee is the hourly fee that you pay for Heavy Utilization, whether or not you're using the Reserved Instance. For more information about the availability of Reserved Instances offerings based on utilization, see Choosing Reserved Instances Based on Your Usage Plans (p. 204).

**Setting a Pricing Schedule**

You can set different upfront fees (prices) that are based on when your Reserved Instance sells. You can specify one price if the Reserved Instance sells immediately, and you can specify another price if the Reserved Instance were to sell in any subsequent month. Since the value of Reserved Instances decreases over time, by default, AWS will set prices to decrease linearly—that is, the price drops in equal increments month over month. You can choose to set the prices differently.

For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount you would accept if a customer were to purchase that Reserved Instance with nine months remaining, and you could set another price with five months remaining, and yet another price with one month remaining.

**Listing Your Reserved Instance**

You can list the Reserved Instances you want to sell in the Reserved Instance Marketplace by using the AWS Management Console, the Amazon EC2 CLI, or the Amazon EC2 API.

**AWS Management Console**

**To list a Reserved Instance in the Reserved Instance Marketplace**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click **Reserved Instances** in the **Navigation** pane.
   
   The **Reserved Instances** page displays a list of your account's instances.
3. Select the Reserved Instances you want to list on the marketplace, and click **Sell Reserved Instances**.

**Note**

If you have not completed the Reserved Instance Marketplace seller registration process, you will be prompted to complete this process now. For information about the seller registration process, see Registering as a Seller (p. 241).
4. In the Configure Your Reserved Instance Listing page, for Number to List, set the number of instances to sell and, for Your Price, set the upfront price for the remaining time period.

You can see how the value of your Reserved Instance will change over the remainder of the term by clicking the arrow on the left of the Months Remaining column. By default, AWS sets the price to decrease linearly. This means the price drops by equal increments each month.

5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, click Reset. Click Continue when you are finished configuring your listing.

6. When you are satisfied with the details of your listing as displayed by the Confirm Your Reserved Instance Listing page, click List Reserved Instance.
You will get a confirmation that your listing is being processed.

7. To view the details of your Reserved Instance listing, on the Reserved Instances page, select the Reserved Instance you want to view, and click the My Listings tab.

Amazon EC2 CLI

To list a Reserved Instance in the Reserved Instance Marketplace

1. Get a list of your Reserved Instances by calling ec2-describe-reserved-instances.

PROMPT> ec2-describe-reserved-instances --headers

Amazon EC2 returns output similar to the following:

```

Select the Reserved Instance ID of the Reserved Instance you want to list in the Reserved Instance Marketplace.

2. Specify the Reserved Instance ID of the Reserved Instance you want to list and call `ec2-create-reserved-instances-listing`. You have to specify the following required parameters:
   - Reserved Instance ID
   - Instance count
   - MONTH:PRICE

The command should look like this example:

```bash
PROMPT> ec2-create-reserved-instances-listing --reserved-instance b847fa93-c736-4eae-bca1-3147example --instance-count 1 05:01.20 04:01.00 01:00.75 -headers

Canceling and Changing Your Listings

After listing your Reserved Instances in the Reserved Instance Marketplace, you can manage your listing using the AWS Management Console (p.255), the Amazon EC2 CLI (p.256), or the Amazon EC2 API (p.258). You can view details of your listing. You also can cancel your listing, as long as it hasn't been purchased yet.

Currently, you cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.

In this section, we will show you how to perform the tasks of viewing, canceling and changing your Reserved Instance Marketplace listings, using the console, the CLI, and the API.

AWS Management Console

To view your listing

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Reserved Instances in the Navigation pane.
3. Right-click your Reserved Instance.
4. Click the My Listings tab. You will see details about the Reserved Instance listing you selected.

To cancel your listing

You can cancel your listing at any time, as long as it's in the active state. You cannot cancel the listing if it's already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances will be removed from the listing.
1. Go to the Reserved Instances page in the Amazon EC2 console, and right-click your Reserved Instance.

2. On the My Listings tab, click Cancel Listing.

To change your listing

Currently, you cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.

1. Cancel your active Reserved Instance listing. For more information, see the previous procedure.
2. Create a new listing. For more information, see Listing Your Reserved Instance (p. 246).

Amazon EC2 CLI

To view your listing

- Run `ec2-describe-reserved-instances-listing` to get details about your listing.

```shell
PROMPT> ec2-describe-reserved-instances-listings
```

Amazon EC2 returns output similar to the following:

```shell

To cancel your listing

You can cancel your listing at any time, as long as it’s in the active state. You cannot cancel the listing if it’s already matched or being processed for a sale.

- Run CancelReservedInstancesListing to cancel your listing 5ec28771-05ff-4b9b-aa31-9e57dexample and remove it from the Reserved Instance Marketplace.

The command should look like this example:

```plaintext
https://ec2.amazonaws.com/?Action=CancelReservedInstancesListing
&ReservedInstancesListingId.0=5ec28771-05ff-4b9b-aa31-9e57dexample

To change your listing

Currently, you cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.

1. Cancel your active Reserved Instance listing. For more information, see the previous procedure.
2. Create a new listing. For more information, see Listing Your Reserved Instance (p. 246).

After Your Reserved Instance Is Sold

Topics
- Reserved Instance Listing States (p. 265)
- Lifecycle of a Listing (p. 265)
- Getting Paid (p. 266)
- Notifications (p. 266)

When your Reserved Instance is sold, AWS will send you an email notification. Each day that there is any kind of activity (for example, you create a listing; you sell a listing; or AWS sends funds to your account), you will get one email notification capturing all the activities of the day. For more information, see Notifications (p. 266).

You can track the status of your Reserved Instance listings by looking at the My Listings tab of the selected Reserved Instance on the Reserved Instance page in the Amazon EC2 console. The tab contains the Listing State as well as information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and cancelled. You can also use the ec2-describe-reserved-instances-listings CLI command or the DescribeReservedInstancesListings API call, with the appropriate filter to obtain information about your Reserved Instance listings.
Reserved Instance Listing States

Listing State displays the current status of your Reserved Instance listings:

- **Active**—The listing is available for purchase.
- **Cancelled**—The listing is canceled and won't be available for purchase in the marketplace.
- **Closed**—The Reserved Instance is not listed. A Reserved Instance might be Closed because the sale of the listing was completed.

The information displayed by Listing State is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the State column in the Reserved Instance page. This State information is about your Reserved Instance. For more information, see Reserved Instance States (p. 225).

Lifecycle of a Listing

Now that you have created a listing, let's walk through what happens when your listing sells.

When all the instances in your listing are matched and sold, the My Listings tab shows that your Total instance count matches the count listed under Sold, there are no Available instances left for your listing, and its Status is closed.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the Reserved Instances listing ID and the listing that it represents, which now has an instance count of fewer instances for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as closed.

For example, let's say you created a listing Reserved Instances listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample with an instance count of 5.

Your My Listings tab in the Reserved Instance page of the Amazon EC2 console will display the listing this way:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total instance count = 5
- Sold = 0
- Available = 5
- Status = active

Let's say that a buyer purchases two of the instances, which leaves a count of three instances still available for sale. As a result of this partial sale, AWS creates a new Reserved Instance with an instance count of three to represent the remaining three that are still for sale.

This is how your listing will look in your My Listings tab:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total instance count = 5
- Sold = 2
- Available = 3
- Status = active
If you decide to cancel your listing and a portion of that listing has already sold, the cancellation is not effective on the portion that has been sold. Only the portion of the listing not yet sold will no longer be available in the Reserved Instance Marketplace.

**Getting Paid**

As soon as AWS receives funds from the buyer of your Reserved Instance, AWS sends a message to your email address—that is, the email address associated with the account that is registered as owner of the Reserved Instance that was sold.

AWS sends an Automated Clearing House (ACH) wire transfer to the bank account that you specified when you registered for the Reserved Instance Marketplace. Typically, this transfer occurs between one to three days after your Reserved Instance has been matched. You can view the state of this disbursement by viewing your Reserved Instance disbursement report. Disbursements take place once a day. Keep in mind that you will not be able to receive disbursements until AWS has received verification from your bank. This period can take up to two weeks.

The Reserved Instance you sold will continue to appear in the results of `DescribeReservedInstances` calls you make.

**Notifications**

As a seller in the Reserved Instance Marketplace, you will receive an email digest of the Reserved Instance Marketplace activities pertaining to your account. On any given day, you will receive one email digest, and you will only receive this email if one or a combination of activities occurred that day:

- You created a new listing in the Reserved Instance Marketplace.
- You sold one or more of the Reserved Instances you listed.
- AWS posted a disbursement to your bank account as a result of a sale of part or all of your listing in the Reserved Instance Marketplace.

Your email digest will look similar to the following:

**Requirements Checklist for Reserved Instances**

Amazon EC2 Reserved Instances and the Reserved Instance Marketplace can be a powerful and cost-saving strategy for running your business. However, before you use Reserved Instances or the Reserved Instance Marketplace, ensure that you meet the requirements for purchase and sale. You also must understand the details and restrictions on certain elements of Reserved Instances and the Reserved Instance Marketplace—including seller registration, banking, using the AWS free tier, dealing with cancelled instances, and so on. Use this topic as a checklist for buying and selling Reserved Instances, and for buying and selling in the Reserved Instance Marketplace.
Reserved Instances

- **AWS account**—You need to have an AWS account in order to purchase Reserved Instances. If you don't have an AWS account, you should read and complete the instructions described in Getting Started with Amazon EC2 Linux Instances (p. 24), which provides information on signing up for your Amazon EC2 account and credentials.

- **AWS free tier**—The AWS free usage tier is available for new AWS accounts. If you are using the AWS free usage tier to run Amazon EC2 instances, and then you purchase a Reserved Instance, you will be charged for the Reserved Instance under standard pricing guidelines. For information about the free tier and the applicable services and usage amounts, see AWS Free Usage Tier.

Buying Reserved Instances

- **Usage fee for Heavy Utilization**—With Light Utilization and Medium Utilization Reserved Instances, you pay a one-time upfront fee and then only pay the hourly price when you use the instance. With Heavy Utilization Reserved Instances, you pay a low, one-time upfront fee and commit to paying an hourly rate for every hour of the Reserved Instance's term whether or not you use it. For information, see Choosing Reserved Instances Based on Your Usage Plans (p. 204).

- **Tiered discounts on purchases**—The Reserved Instance pricing tier discounts only apply to purchases made from AWS. These discounts do not apply to purchases of third-party Reserved Instances. For information, see Understanding Reserved Instance Pricing Tiers (p. 205).

- **Cancellation of purchase**—Before you confirm your purchase, review the details of the Reserved Instances that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase. However, you can sell the Reserved Instance if your needs change. For information, see Selling Your Reserved Instances (p. 245).

Selling Reserved Instances and the Reserved Instance Marketplace

- **Seller requirement**—To become a seller in the Reserved Instance Marketplace, you must register as a seller. For information, see Selling Your Reserved Instances (p. 245).

- **Bank requirement**—AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see Your Bank (p. 242).

- **Tax requirement**—Sellers who have 200 or more transactions or who plan to sell $20,000 or more in Reserved Instances will have to provide additional information about their business for tax reasons. For information, see Tax Information (p. 243).

- **Minimum selling**—The minimum price allowed in the Reserved Instance Marketplace is $1.01.

- **When Reserved Instances can be sold**—Reserved Instances can be sold only after AWS has received the upfront payment and the Reserved Instance has been active (you've owned it) for at least 30 days. In addition, there must be at least a month remaining in the term of the Reserved Instance you are listing.

- **Modifying your listing**—Currently, you cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see Canceling and Changing Your Listings (p. 255). You also can change your Reserved Instances before listing them. For information, see Modifying Your Reserved Instances (p. 230).

- **Selling discounted Reserved Instances**—Amazon EC2 Reserved Instances purchased at a reduced cost resulting from a tiering discount cannot be sold in the Reserved Instance Marketplace. For more information, see Reserved Instance Marketplace (p. 212).

- **Service fee**—AWS will charge you a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the marketplace. (The upfront price is the price the seller is charging for his Reserved Instance.)
• **Other AWS Reserved Instances**—Only Amazon EC2 Reserved Instances can be sold in the Reserved Instance Marketplace. Other AWS Reserved Instances, such as Amazon Relational Database Service (Amazon RDS) and Amazon ElastiCache Reserved Instances cannot be sold in the Reserved Instance Marketplace.

## Instance Metadata and User Data

*Instance metadata* is data about your instance that you can use to configure or manage the running instance. Instance metadata is divided into categories. For more information, see [Instance Metadata Categories](#p-275).

EC2 instances can also include *dynamic data*, such as an instance identity document that is generated when the instance is launched. For more information, see [Dynamic Data Categories](#p-278).

You can also access the *user data* that you supplied when launching your instance. For example, you can specify parameters for configuring your instance, or attach a simple script. You can also use this data to build more generic AMIs that can be modified by configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same AMI and retrieve their content from the Amazon S3 bucket you specify in the user data at launch. To add a new customer at any time, simply create a bucket for the customer, add their content, and launch your AMI. If you launch more than one instance at the same time, the user data is available to all instances in that reservation.

Because you can access instance metadata and user data from within your running instance, you do not need to use the Amazon EC2 console or the CLI tools. This can be helpful when you’re writing scripts to run from within your instance. For example, you can access your instance’s local IP address from within the running instance to manage a connection to an external application.

**Important**

Although you can only access instance metadata and user data from within the instance itself, the data is not protected by cryptographic methods. Anyone who can access the instance can view its metadata. Therefore, you should take suitable precautions to protect sensitive data (such as long-lived encryption keys). You should not store sensitive data, such as passwords, as user data.

For more information about adding user data when you launch an instance, see [Launching an Instance](#p-300). You can add or modify user data on Amazon EBS-backed instances when they're stopped. For more information about adding user data to a stopped instance, see [Modifying a Stopped Instance](#p-321).

When you are adding user data, take note of the following:

- User data is treated as opaque data: what you give is what you get back. It is up to the instance to be able to interpret it.
- User data is limited to 16 KB. This limit applies to the data in raw form, not base64-encoded form.
- User data must be base64-encoded before being submitted to the API. The API command line tools perform the base64 encoding for you. The data is decoded before being presented to the instance. For more information about base64 encodings, go to [http://tools.ietf.org/html/rfc4648](http://tools.ietf.org/html/rfc4648).

Retrieving Instance Metadata

To view all categories of instance metadata from within a running instance, use the following URI:

```
```

Note that you are not billed for HTTP requests used to retrieve instance metadata and user data.

On a Linux instance, you can use a tool such as cURL, or if your instance supports it, the GET command; for example:

```
```

```
```

You can also download the Instance Metadata Query tool, which allows you to query the instance metadata without having to type out the full URI or category names:

```
http://aws.amazon.com/code/1825
```

On a Windows instance, you can install a tool such as GNU Wget or cURL to retrieve instance metadata at the command line, or you can copy and paste the URI into a browser. If you do not want to install any third-party tools, you can use PowerShell cmdlets to retrieve the URI. For example, if you are running version 3.0 or later of PowerShell, use the following cmdlet:

```
```

**Important**

If you do install a third-party tool on a Windows instance, ensure that you read the accompanying documentation carefully, as the method of calling the HTTP and the output format might be different from what is documented here.

All metadata is returned as text (content type text/plain). A request for a specific metadata resource returns the appropriate value, or a 404 - Not Found HTTP error code if the resource is not available.

A request for a general metadata resource (the URI ends with a /) returns a list of available resources, or a 404 - Not Found HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

**Examples of Retrieving Instance Metadata**

The following are examples of requests and responses on a Linux instance.

This example gets the available versions of the instance metadata. These versions do not necessarily correlate with an Amazon EC2 API version. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

```
$ curl http://169.254.169.254/
1.0
2007-01-19
2007-03-01
2007-08-29
2007-10-10
```
This example gets the top-level metadata items. Some items are only available for instances in a VPC. For more information about each of these items, see Instance Metadata Categories (p. 275).

Retrieving User Data

To retrieve user data, use the following URI:

http://169.254.169.254/latest/user-data

Requests for user data returns the data as it is (content type application/x-octetstream).

This shows an example of returning comma-separated user data.

$ curl http://169.254.169.254/latest/user-data
1234,john,reboot,true | 4512,richard, | 173,,,
This shows an example of returning line-separated user data.

```
$ curl http://169.254.169.254/latest/user-data
[general]
instances: 4

[instance-0]
s3-bucket: <user_name>

[instance-1]
reboot-on-error: yes
```

## Retrieving Dynamic Data

To retrieve dynamic data from within a running instance, use the following URI:

```
```

This example shows how to retrieve the high-level instance identity categories:

```
pkcs7
signature
document
```

## Example: AMI Launch Index Value

This example demonstrates how you can use both user data and instance metadata to configure your instances.

Alice wants to launch four instances of her favorite Linux database AMI, with the first acting as master and the remaining three acting as replicas. When she launches them, she wants to add user data about the replication strategy for each replicant. She is aware that this data will be available to all four instances, so she needs to structure the user data in a way that allows each instance to recognize which parts are applicable to it. She can do this using the `ami-launch-index` instance metadata value, which will be unique for each instance.

Here is the user data that Alice has constructed:

```
replicate-every=1min | replicate-every=5min | replicate-every=10min
```

The `replicate-every=1min` data defines the first replicant's configuration, `replicate-every=5min` defines the second replicant's configuration, and so on. Alice decides to provide this data as an ASCII string with a pipe symbol (|) delimiting the data for the separate instances.

Alice launches four instances, specifying the user data:

```
PROMPT> ec2-run-instances ami-2bb65342 -n 4 -d "replicate-every=1min | replicate-every=5min | replicate-every=10min"
RESERVATION     r-fea54097      598916040194    default

```

API Version 2014-02-01

272
After they're launched, all instances have a copy of the user data and the common metadata shown here:

- AMI id: ami-2bb65342
- Reservation ID: r-fea54097
- Public keys: none
- Security group name: default
- Instance type: m1.small

However, each instance has certain unique metadata.

Alice can use the ami-launch-index value to determine which portion of the user data is applicable to a particular instance.

1. She connects to one of the instances, and retrieves the ami-launch-index for that instance to ensure it is one of the replicants:

   
   ```bash
   2
   ```

2. She saves the ami-launch-index as a variable:

   ```bash
   ```

3. She saves the user data as a variable:

   ```bash
   $ user_data=`curl http://169.254.169.254/latest/user-data/`
   ```

4. Finally, Alice runs a Linux cut command to extract the portion of the user data that is applicable to that instance:

   ```bash
   $ echo $user_data | cut -d"\" -f"$ami_launch_index"
   replicate-every=5min
   ```
# Instance Metadata Categories

Importing and Exporting Instances

You can use the Amazon Web Services (AWS) VM Import/Export tools to import virtual machine (VM) images from your local environment into AWS and convert them into ready-to-use Amazon EC2 instances. Later, you can export the VM images back to your local environment. VM Import/Export allows you to leverage your existing investments in the virtual machines that you have built to meet your IT security, configuration management, and compliance requirements by bringing those VMs into Amazon Elastic Compute Cloud (Amazon EC2) as ready-to-use instances. VM Import/Export is compatible with Citrix Xen, Microsoft Hyper-V, or VMware vSphere virtualization environments.

VM Import/Export can be used to migrate applications and workloads, copy your VM image catalog, or create a disaster recovery repository for VM images.

- **Migrate existing applications and workloads to Amazon EC2**—You can migrate your VM-based applications and workloads to Amazon EC2 and preserve their software and configuration settings. After you import your applications and workloads into an Amazon EC2 instance, you can create Amazon Machine Images (AMIs) and run multiple copies of the same image. You can also create snapshots and use them to back up your data. You can use AMI and snapshot copies to replicate your applications and workloads around the world. For more information about AMI copy, see Copying an AMI (p. 80).

- **Copy your VM image catalog to Amazon EC2**—You can copy your existing VM image catalog into Amazon EC2. If you maintain a catalog of approved VM images, you can copy your image catalog to Amazon EC2 and create Amazon EC2 instances from the imported VM images. Your existing software, including products that you have installed such as anti-virus software, intrusion detection systems, and so on, can be imported along with your VM images. You can use the resulting Amazon EC2 instances to create Amazon EC2 AMIs. You can use the AMIs as your image catalog within Amazon EC2.

- **Create a disaster recovery repository for VM images**—You can import your local VM images into Amazon EC2 for backup and disaster recovery purposes. You can store the imported images as Amazon Elastic Block Store (Amazon EBS)-backed AMIs so they're ready to launch in Amazon EC2 when you need them. If your local environment suffers an event, you can quickly launch your instances to preserve business continuity while simultaneously exporting them to rebuild your local infrastructure.

The following diagram shows the process of exporting a VM from your on-premises virtualization environment to AWS.
Prerequisites

Before you begin the process of exporting an instance from your virtualization environment or importing and exporting a VM from Amazon EC2, you need to be aware of the operating systems and image formats that AWS supports, and understand the limitations on exporting instances and volumes.

You will also need to download and install the Amazon EC2 command line tools before you use the command line interface (CLI) or the API to export your instance. For more information, see Setting Up the Amazon EC2 Tools.

Operating Systems—The following operating systems can be imported into and exported from Amazon EC2:

Windows (32- and 64-bit)
- Microsoft Windows Server 2003 (Standard, Datacenter, Enterprise) with Service Pack 1 (SP1) or later.
- Microsoft Windows Server 2003 R2 (Standard, Datacenter, Enterprise).
- Microsoft Windows Server 2008 (Standard, Datacenter, Enterprise).
- Microsoft Windows Server 2008 R2 (Standard, Datacenter, Enterprise).
- Microsoft Windows Server 2012 (Standard, Datacenter).

Linux/Unix (64-bit)
- Red Hat Enterprise Linux (RHEL) 5.1-6.5

Note
VM Import supports license portability for RHEL instances. Your existing RHEL licenses are imported along with their associated RHEL instance. For more information about eligibility for Red Hat Cloud Access, see Eligibility at the Red Hat website.

- CentOS 5.1-6.5
Importing Image Formats into Amazon EC2—AWS supports the following image formats for importing both volumes and instances into Amazon EC2:

- RAW format for importing volumes and instances.
- Virtual Hard Disk (VHD) image formats, which are compatible with Microsoft Hyper-V and Citrix Xen virtualization products.
- ESX Virtual Machine Disk (VMDK) image formats, which are compatible with VMware ESX and VMware vSphere virtualization products.

Exporting Image Formats from Amazon EC2—AWS supports the following image formats for exporting both volumes and instances from Amazon EC2:

- Stream-optimized ESX Virtual Machine Disk (VMDK) image format, which is compatible with VMware ESX and VMware vSphere versions 4 and 5 virtualization products.
- Open Virtual Appliance (OVA) image format, which is compatible with VMware vSphere versions 4 and 5.
- Virtual Hard Disk (VHD) image format, which is compatible with Citrix Xen and Microsoft Hyper-V virtualization products.

Instance Types that You Can Import a VM into—AWS supports importing Windows instances into any instance type. Linux instances can be imported into the following instance types:

- c3.large
- c3.xlarge
- c3.2xlarge
- c3.4xlarge
- cc1.4xlarge
- cc2.8xlarge
- cg1.4xlarge
- cr1.8xlarge
- hi1.4xlarge
- hs1.8xlarge
- i2.xlarge
- i2.2xlarge
- i2.4xlarge
- m3.medium
- m3.large
- m3.xlarge
- m3.2xlarge

Known Limitations for Importing a VM into Amazon EC2—Importing instances and volumes is subject to the following limitations:

- You can have up to five import tasks in progress at the same time per region.
- Imported instances create EC2 instances that use Hardware Virtual Machine (HVM) virtualization. Creating instances that use Paravirtual (PV) virtualization using VM Import is not supported. Linux PVHVM drivers are supported within imported instances.
• Imported Red Hat Enterprise Linux (RHEL) instances must use Cloud Access (BYOL) licenses.
• Imported Linux instances must use 64-bit images. Importing 32-bit Linux images is not supported.
• Typically, you import a compressed version of a disk image; the expanded image cannot exceed 1 TB.
• Make sure your VM only uses a single disk. Importing a VM with more than one disk is not supported. For Linux VMs, /boot and / can be located in different partitions, but they need to be on the same disk.

We suggest that you import the VM with only the boot volume, and import any additional disks using the `ec2-import-volume` command. After the `ImportInstance` task is complete, use the `ec2-attach-volume` command to associate the additional volumes with your instance.

• VHD images must use the dynamic VHD image format. Fixed or differencing VHD image formats are unsupported.
• Make sure that you have at least 250 MB of available disk space for installing drivers and other software on any VM you want to import into an Amazon EC2 instance running Microsoft Windows.
• Imported instances automatically have access to the Amazon EC2 instance store, which is temporary disk storage from disks that are physically attached to the host computer. You cannot disable this during import. For more information about instance storage, see Amazon EC2 Instance Store (p. 582).
• Tasks must complete within 7 days of the start date.
• Multiple network interfaces are not currently supported. When converted and imported, your instance will have a single virtual NIC using DHCP for address assignment.
• Internet Protocol version 6 (IPv6) IP addresses are not supported.
• For vCenter 4.0 and vSphere 4.0 users, remove any attached CD-ROM images or ISOs from the virtual machine.
• Amazon VM Import does not install the single root I/O virtualization (SR-IOV) drivers on the c3 and i2 instance types. These drivers are not required unless you plan to use enhanced networking, which provides higher performance (packets per second), lower latency, and lower jitter. To enable enhanced networking on a c3 or i2 instance type after you import your VM, see Enabling Enhanced Networking on Linux Instances in a VPC (p. 516).

Known Limitations for Exporting a VM from Amazon EC2—Exporting instances and volumes is subject to the following limitations:

• You cannot export Amazon Elastic Block Store (Amazon EBS) data volumes.
• You cannot export an instance that has more than one virtual disk.
• You cannot export an instance that has more than one network interface.
• You cannot export an instance unless it was previously imported into AWS.

Importing a VM into Amazon EC2

There are two ways you can launch an instance in Amazon EC2. You can launch an instance from an Amazon Machine Image (AMI), or, you can launch an instance from a virtual machine (VM) that you imported from a virtualization environment such as Citrix Xen, Microsoft Hyper-V, or VMWare vSphere. This section covers importing a VM and launching it as an Amazon EC2 instance. For more information about how to launch an Amazon EC2 instance from an AMI, see Launch Your Instance (p. 300).

To use your VM as an instance in Amazon EC2, you must first export it from the virtualization environment, and then import it to Amazon EC2 using the Amazon EC2 command line interface (CLI) or API tools.

Whether you use the CLI or the API, you will follow the same steps for importing VMs or volumes into Amazon EC2. This is the process for using the CLI:

1. Install the CLI. For more information, see Step 1: Install the Amazon EC2 CLI (p. 283).
2. Prepare the VM for import to Amazon EC2. For more information, see Step 2: Prepare Your VM (p. 283).
3. Export the VM from the virtualization environment. For more information, see Step 3: Export Your VM from Its Virtual Environment (p. 284).

4. Import the VM into Amazon EC2. For information, see Step 4: Importing Your VM into Amazon EC2 (p. 284).

5. Launch the instance in Amazon EC2. For more information, see Step 5: Launch the instance in Amazon EC2 (p. 291).

### Step 1: Install the Amazon EC2 CLI

You need to install the Amazon EC2 CLI to import your Citrix, Microsoft Hyper-V, or VMware vSphere virtual machines into Amazon EC2 or to export them from Amazon EC2. If you haven't already installed the Amazon EC2 CLI, see Setting Up the Amazon EC2 Tools.

You'll use the following Amazon EC2 commands to import or export a VM:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ec2-import-instance</code></td>
<td>Creates a new import instance task using metadata from the specified disk image and imports the instance to Amazon EC2.</td>
</tr>
<tr>
<td><code>ec2-import-volume</code></td>
<td>Creates a new import volume task using metadata from the specified disk image and imports the volume to Amazon EC2.</td>
</tr>
<tr>
<td><code>ec2-resume-import</code></td>
<td>Resumes the upload of a disk image associated with an import instance or import volume task ID.</td>
</tr>
<tr>
<td><code>ec2-describe-conversion-tasks</code></td>
<td>Lists and describes your import tasks.</td>
</tr>
<tr>
<td><code>ec2-cancel-conversion-task</code></td>
<td>Cancels an active import task. The task can be the import of an instance or volume.</td>
</tr>
<tr>
<td><code>ec2-delete-disk-image</code></td>
<td>Deletes a partially or fully uploaded disk image for import from an Amazon S3 bucket.</td>
</tr>
<tr>
<td><code>ec2-create-image-export-task</code></td>
<td>Exports a running or stopped instance to an Amazon S3 bucket.</td>
</tr>
<tr>
<td><code>ec2-cancel-export-task</code></td>
<td>Cancels an active export task.</td>
</tr>
<tr>
<td><code>ec2-describe-export-tasks</code></td>
<td>Lists and describes your export tasks, including the most recent canceled and completed tasks.</td>
</tr>
</tbody>
</table>

For information about these commands and other Amazon EC2 commands, see the Amazon Elastic Compute Cloud Command Line Reference.

### Step 2: Prepare Your VM

Use the following guidelines to configure your VM before exporting it from the virtualization environment.

- Review the prerequisites. For more information, see Prerequisites (p. 280).
- Disable any antivirus or intrusion detection software on your VM. These services can be re-enabled after the import process is complete.
- Disconnect any CD-ROM drives (virtual or physical).
Set your network to DHCP instead of a static IP address. If you want to assign a static private IP address, be sure to use a non-reserved private IP address in your VPC subnet. Amazon Virtual Private Cloud (Amazon VPC) reserves the first four private IP addresses in a VPC subnet.

Shut down your VM before exporting it.

**Windows**

- Enable Remote Desktop (RDP) for remote access.
- Make sure that your host firewall (Windows firewall or similar), if configured, allows access to RDP. Otherwise, you will not be able to access your instance after the import is complete.
- Make sure that the administrator account and all other user accounts use secure passwords. All accounts must have passwords or the importation might fail.
- Make sure that your Windows VM has .NET Framework 3.5 installed, as required by Amazon Windows EC2Config Service.
- Do not run System Preparation (Sysprep) on your Windows VM images. We recommend that you import the image and then use the Amazon EC2 Config service to run Sysprep.
- Disable Autologon on your Windows VM.
- Make sure that there are no pending Microsoft updates, and that the computer is not set to install software when it reboots.

**Linux**

- Enable Secure Shell (SSH) for remote access.
- Make sure that your host firewall (such as Linux iptables) allows access to SSH. Otherwise, you will not be able to access your instance after the import is complete.
- Make sure that you have configured a non-root user to use public key-based SSH to access your instance after it is imported. The use of password-based SSH and root login over SSH are both possible, but not recommended. The use of public keys and a non-root user is recommended because it is more secure. VM Import will not configure an `ec2-user` account as part of the import process.
- Make sure that your Linux VM uses GRUB (GRUB legacy) or GRUB 2 as its bootloader.
- Make sure that your Linux VM uses a root filesystem is one of the following: EXT2, EXT3, EXT4, Btrfs, JFS, or XFS.

### Step 3: Export Your VM from Its Virtual Environment

After you have prepared your VM for export, you can export it from your virtualization environment. For information about how to export a VM from your virtualization environment, see the documentation for Citrix, Microsoft Hyper-V, or VMware vCenter virtualization environment.

**Citrix:** For more information, see [Export VMs as OVF/OVA](#) at the Citrix website.

**Microsoft Hyper-V:** For more information, see [Hyper-V - Export & Import](#) at the Microsoft website.

**VMware:** For more information, see [Export an OVF Template](#) at the VMware website.

### Step 4: Importing Your VM into Amazon EC2

After exporting your VM from your virtualization environment, you can import it into Amazon EC2. The import process is the same regardless of the origin of the VM.

Here are some important things to know about your VM instance, as well as some security and storage recommendations:
Amazon EC2 automatically assigns a DHCP IP address to your instance. The DNS name and IP address are available via the `ec2-describe-instances` command when the instance starts running.

Your instance has only one Ethernet network interface.

To specify an Amazon Virtual Private Cloud (Amazon VPC) subnet to use when you create the import task, use the `--subnet subnet_id` option with the `ec2-import-instance` command; otherwise, your instance will use a public IP address. We recommend that you use a restrictive security group to control access to your instance. For more information about the `--subnet subnet_id` option, see `ec2-import-instance`.

We recommend that your Windows instances contain strong passwords for all user accounts. We recommend that your Linux instances use public keys for SSH.

For Windows instances, we recommend that you install the Amazon Windows EC2Config Service after you import your virtual machine into Amazon EC2.

**To import a virtual machine**

You can import a VM into Amazon EC2. If the import of the VM is interrupted, you can use the `ec2-resume-import` command to resume the import from where it stopped. For more information, see Resuming an Upload (p. 289).

- Use `ec2-import-instance` to create a new import instance task.

  The syntax of the command is as follows:

  ```
  ec2-import-instance DISK_IMAGE_FILENAME -t INSTANCETYPE -f FORMAT -a ARCHITECTURE-SYSTEM -b S3_BUCKET_NAME -o OWNER -w SECRETKEY -p PLATFORM_NAME
  ```

  The following command creates an import instance task that imports a Windows Server 2008 SP2 (32-bit) VM.

  ```
  Note
  The example uses the VMDK format. You can also use VHD or RAW.
  ```

  ```
  ec2-import-instance ./WinSvr8-2-32-disk1.vmdk -f VMDK -t m1.small -a i386 -b myawsbucket -o AKIAIOSFODNN7EXAMPLE -w wJalrXUtntFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY -p Windows
  ```

  This request uses the VMDK file, `WinSvr8-2-32-disk1.vmdk`, to create the import task. If you do not specify a size for the requesting volume, the default size of 4 GB is used. The output is similar to the following example.

  ```
  Requesting volume size: 25 GB
  Disk image format: Stream-optimized VMDK
  Converted volume size: 26843545600 bytes (25.00 GiB)
  Requested EBS volume size: 26843545600 bytes (25.00 GiB)

The following example creates an import instance task that imports a 64-bit Linux virtual machine:

```
ec2-import-instance rhel6.4-64bit-disk.vhd -O AKIAIOSFODNN7EXAMPLE –W wJalrXUtFEMIK7MDENG/bPXRfiCYEXAMPLEKEY -f vhd -p Linux -o AKIAI44QH8DH BEXAMPLE -w je7MtGc1wBF/22p9UtK/h3yCo8nvbEXAMPLEKEY -t m3.xlarge -a x86_64 -b myawsbucket --region us-east-1
```

This request uses the VHD file, `rhel6.4-64bit-disk.vhd`, to create the import task. The output is similar to the following example:

```
Requesting volume size: 8 GB
TaskType IMPORTINSTANCE TaskId import-i-ffnzq636 ExpirationTime 2013-12-12T22:55:18Z Status active StatusMessage Pending

```

The disk image for import-i-ffnzq636 has been uploaded to Amazon S3 where it is being converted into an EC2 instance. You may monitor the progress of this task by running `ec2-describe-conversion-tasks`. When the task is completed, you may use `ec2-delete-disk-image` to remove the image from S3.

### Checking on the Status of Your Import Task

The `ec2-describe-conversion-tasks` command returns the status of an import task. Status values include the following:

- **active**—Your instance or volume is still importing.
- **cancelling**—Your instance or volume is still being canceled.
- **cancelled**—Your instance or volume is canceled.
- **completed**—Your instance or volume is ready to use.

The imported instance is in the stopped state. You use `ec2-start-instance` to start it. For more information, see `ec2-start-instances` in the [Amazon Elastic Compute Cloud Command Line Reference](https://docs.aws.amazon.com/cli/latest/reference/ec2/start-instances.html).
To check the status of your import task

- Use `ec2-describe-conversion-task` to return the status of the task. The syntax of the command is as follows:

```
ec2-describe-conversion-tasks --region REGIONID TASKID
```

The following example enables you to see the status of your import instance task.

```
ec2-describe-conversion-tasks --region us-east-1 import-i-ffvko9js
```

The following response shows that the IMPORTINSTANCE status is active, and 73747456 bytes out of 893968896 have been converted.

**Note**

The IMPORTINSTANCE status is what you use to determine the final status. The DISKIMAGE status will be completed for a period of time before the IMPORTINSTANCE status is completed.

You can now use commands such as `ec2-stop-instance`, `ec2-start-instance`, `ec2-reboot-instance`, and `ec2-terminate-instance` to manage your instance.

**Note**

By default, when you terminate an instance, Amazon EC2 does not delete the associated Amazon EBS volume. You can optionally use the `ec2-modify-instance-attribute` command to change this behavior.
Importing Your Volumes into Amazon EBS

This section describes how to import your data storage into Amazon EBS, and then attach it to one of your existing EC2 instances. Amazon EC2 supports importing RAW and VMDK disk formats.

**Important**
We recommend using Amazon EC2 security groups to limit network access to your imported instance. Configure a security group to allow only trusted EC2 instances and remote hosts to connect to RDP and other service ports. For more information about security groups, see Amazon EC2 Security Groups (p. 440).

After you have exported your virtual machine from the virtualization environment, importing the volume to Amazon EBS is a single-step process. You create an import task and upload the volume.

**To import a volume into Amazon EBS**

1. Use `ec2-import-volume` to create a task that allows you to upload your volume into Amazon EBS. The syntax of the command is as follows:

   ```
   $ ec2-import-volume DISK_IMAGE_FILENAME -f FORMAT -s SIZE-IN-GB -z AVAILABILITY_ZONE -b S3_BUCKET_NAME -o OWNER -w SECRETKEY
   ```

   The following example creates an import volume task for importing a volume to the us-east-1 region in the d availability zone.

   ```
   ec2-import-volume Win_2008_R1_EE_64.vmdk -f vmdk -s 25 -z us-east-1d -b myawsbucket -o AKIAIOSFODNN7EXAMPLE -w wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
   ```

   **Note**
   The example uses the VMDK format. You can also use VHD or RAW.

   ```
   Requesting volume size: 25 GB
   Disk image format: Stream-optimized VMDK
   Converted volume size: 26843545600 bytes (25.00 GiB)
   Requested EBS volume size: 26843545600 bytes (25.00 GiB)
   TaskType IMPORTVOLUME TaskId import-vol-ffut5xv4 ExpirationTime 2011-09-09T15:22:30Z Status active StatusMessage Pending
   DISKIMAGE DiskImageFormat VMDK DiskImageSize 5070303744

   Uploading 5070303744 bytes across 484 parts
   0% |--------------------------------------------------| 100%
   |==================================================|
   Done
   ```

   Amazon EC2 returns a task ID that you use in the next step. In this example, the ID is `import-vol-ffut5xv4`.

2. Use `ec2-describe-conversion-tasks` to confirm that your volume imported successfully.
3. Use `ec2-attach-volume` to attach the Amazon EBS volume to one of your existing EC2 instances. The following example attaches the volume, `vol-2540994c`, to the `i-a149ec4a` instance on the device, `/dev/sde`.

```bash
$ ec2-attach-volume vol-2540994c -i i-a149ec4a -d /dev/sde
ATTACHMENT vol-2540994c i-a149ec4a /dev/sde attaching 2010-03-23T15:43:46+00:00
```

**Resuming an Upload**

Connectivity problems can interrupt an upload. When you resume an upload, Amazon EC2 automatically starts the upload from where it stopped. The following procedure steps you through determining how much of an upload succeeded and how to resume it.

**To resume an upload**

- Use the task ID with `ec2-resume-import` to continue the upload. The command uses the HTTP HEAD action to determine where to resume.

```bash
ec2-resume-import DISK_IMAGE_FILENAME -t TASK_ID -o OWNER -w SECRETKEY
```

The following example resumes an import instance task.

```bash
$ec2-resume-import Win_2008_R1_EE_64.vmdk -t import-i-ffni8aei -o AKIAIOSFODNN7EXAMPLE -w wJalrXUttnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
```

The following shows the output when the import instance task is complete:

```
Disk image size: 5070303744 bytes (4.72 GiB)
Disk image format: Stream-optimized VMDK
Converted volume size: 26843545600 bytes (25.00 GiB)
Requested EBS volume size: 26843545600 bytes (25.00 GiB)
Uploading 5070303744 bytes across 484 parts
0% |--------------------------------------------------| 100%
Done
Average speed was 10.316 MBps
The disk image for import-i-ffni8aei has been uploaded to Amazon S3 where it is being converted into an EC2 instance. You may monitor the progress of this task by running `ec2-describe-conversion-tasks`. When the task is completed, you may use `ec2-delete-disk-image` to remove the image from S3.
```

---

The status in this example is **completed**, which means the import succeeded.
Canceling an Upload

Use `ec2-cancel-conversion-task` to cancel an active import task. The task can be the upload of an instance or a volume. The command removes all artifacts of the import, including uploaded volumes or instances.

If the import is complete or still transferring the final disk image, the command fails and returns an exception similar to the following:

```
Client.CancelConversionTask Error: Failed to cancel conversion task import-i-fh95npoc
```

To cancel an upload task

- Use the task ID of the upload you want to delete with `ec2-cancel-conversion-task`. The following example cancels the upload associated with the task ID `import-i-fh95npoc`.

```
PROMPT> ec2-cancel-conversion-task -region us-east-1 import-i-fh95npoc
```

The output for a successful cancellation is similar to the following:

```
CONVERSION-TASK import-i-fh95npoc
```

You can use the `ec2-describe-conversion-tasks` command to check the status of the cancellation as in the following example:

```
$ ./ec2-describe-conversion-tasks -region us-east-1 import-i-fh95npoc
TaskType        IMPORTINSTANCE  TaskId  import-i-fh95npoc       ExpirationTime
               2010-12-20T18:36:39+00:00       Status  cancelled   InstanceID      i-825063ef
DiskImageFormat VMDK    DiskImageSize   2671981568
VolumeSize      40      AvailabilityZone        us-east-1c  ApproximateBytesConverted       0       Status  cancelled

In this example, the status is `cancelled`. If it were still in process, the status would be `cancelling`.

Cleaning Up After an Upload

You can use `ec2-delete-disk-image` to remove the image file after it is uploaded. If you do not delete it, you will be charged for its storage in Amazon S3.

To delete a disk image

- Use the task ID of the disk image you want to delete with `ec2-delete-disk-image`.

```
PROMPT> ec2-delete-disk-image -region us-east-1 -t import-i-fh95npoc
```

The output for a successful cancellation is similar to the following:

```
DELETE-TASK import-i-fh95npoc
```
Step 5: Launch the instance in Amazon EC2

Now that you have imported the VM into AWS, you can launch it as an Amazon EC2 instance. For more information about how to launch an Amazon EC2 instance, see Launch Your Instance (p. 300).

Exporting Amazon EC2 Instances

Topics
- Export an Instance (p. 291)
- Cancel or Stop the Export of an Instance (p. 292)

If you have previously imported an instance into Amazon EC2, you can use the command line tools to export that instance to Citrix Xen, Microsoft Hyper-V, or VMware vSphere. Exporting an instance that you previously imported is useful when you want to deploy a copy of your EC2 instance in your on-site virtualization environment.

Export an Instance

You can use the Amazon EC2 CLI to export an instance. The `ec2-create-instance-export-task` command gathers all of the information necessary (e.g., instance ID; name of the Amazon S3 bucket that will hold the exported image; name of the exported image; VMDK, OVA, or VHD format) to properly export the instance to the selected virtualization format. The exported file is saved in the Amazon S3 bucket that you designate.

Note
When you export an instance, you are charged the standard Amazon S3 rates for the bucket where the exported VM is stored. In addition, a small charge reflecting temporary use of an Amazon EBS snapshot might appear on your bill. For more information about Amazon S3 pricing, see Amazon Simple Storage Service (S3) Pricing.

To export an instance

1. Create an Amazon S3 bucket for storing the exported instances. The Amazon S3 bucket must grant Upload/Delete and View Permissions access to the `vm-import-export@amazon.com` account. For more information, see Creating a Bucket and Editing Bucket Permissions in the Amazon Simple Storage Service Console User Guide.
2. At a command prompt, type the following command:

   ```bash
   ec2-create-instance-export-task INSTANCE_ID -e TARGET_ENVIRONMENT -f DISK_IMAGE_FORMAT -c CONTAINER_FORMAT -b S3_BUCKET
   ```

   Where:

   - `INSTANCE_ID` is the ID of the instance you want to export.
   - `TARGET_ENVIRONMENT` is VMware, Citrix, or Microsoft.
   - `DISK_IMAGE_FORMAT` is VMDK for VMware or VHD for Microsoft Hyper-V and Citrix Xen.
   - `CONTAINER_FORMAT` may be optionally set to OVA when exporting to VMware.
   - `S3_BUCKET` is the name of the Amazon S3 bucket to which you want to export the instance.
3. To monitor the export of your instance, at the command prompt, type the following command:
Cancel or Stop the Export of an Instance

You can use the Amazon EC2 CLI to cancel or stop the export of an instance up to the point of completion. The `ec2-cancel-export-task` command removes all artifacts of the export, including any partially created Amazon S3 objects. If the export task is complete or is in the process of transferring the final disk image, the command fails and returns an error.

To cancel or stop the export of an instance

- At the command prompt, type: `ec2-cancel-export-task --region REGION_ID TASK_ID`

  Where

  - `REGION_ID` is the ID of the region where the export task was started.
  - `TASK_ID` is the ID of the export task you want to cancel.

Troubleshooting VM Import/Export

When importing or exporting a VM, most errors occur when you attempt to do something that isn’t supported. To avoid these errors, read Prerequisites (p. 280) before you begin an import or an export.

AWS Error Code: InvalidParameter, AWS Error Message: Parameter disk-image-size=0 has an invalid format.

The image format you used is not supported.

Resolution

Retry using one of the supported image formats: RAW, VHD, or VMDK.

Client.UnsupportedOperation: This instance has multiple volumes attached. Please remove additional volumes.

The VM has multiple attached disks.

Resolution

Detach the extra drives and try again. If you need the data on the other volumes, copy the data to the root volume and try to export the VM again.

ClientError: Footers not identical

You attempted to import a fixed or differencing VHD image, or there was an error in creating the VHD image.
Resolution

Ensure that your VM uses a dynamic VHD. Export your VM again and retry importing it into Amazon EC2.

**ClientError: Uncompressed data has invalid length.**

The VMDK file is corrupted.

Resolution

You can try repairing or recreating the VMDK file, or use another one for your import.

**ERROR: Bucket `<MyBucketName>` is not in the `<RegionName>` region, it's in `<RegionName>`.

The Amazon S3 bucket is not in the same region as the instance you want to import.

Resolution

Try adding the `--ignore-region-affinity` option, which ignores whether the bucket's region matches the region where the import task is created. You can also create an Amazon S3 bucket using the Amazon Simple Storage Service console and set the region to the region where you want to import the VM. Run the command again and specify the new bucket you just created.

**ERROR: File uses unsupported compression algorithm 0.**

The VMDK was created using OVA format instead of OVF format.

Resolution

Create the VMDK in OVF format.

**ERROR: This does not appear to be a dynamic VHD image. Image starts with c? Ä.**

The VM you are importing is using the fixed or differencing VHD image format, which is unsupported. VM Import only supports the use of dynamic VHD images.

Resolution

Convert the VHD image into a dynamic VHD and retry importing the VM.

**java.lang.OutOfMemoryError: Java heap space**

There is not enough virtual memory available to launch Java, or the image you are trying to import is too large.

Resolution

If you allocate extra memory to Java, the extra memory will only apply to JVM, but if that setting is specified (explicitly for the EC2 command line tools) it will override the global settings. For example, you can use the following command to allocate 512 MB of extra memory to Java `set EC2_JVMARGS=-Xmx512m`. 

---

API Version 2014-02-01

293
Service.InternalError: An internal error has occurred. Status Code: 500, AWS Service: AmazonEC2

You tried to import an instance that does not have a default VPC without specifying the subnet and Availability Zone.

Resolution

If you’re importing an instance without a default VPC, be sure to specify the subnet and Availability Zone.

FirstBootFailure: This import request failed because the Windows instance failed to boot and establish network connectivity.

When you import a VM using the `ec2-import-instance` command, the import task might stop before its completed, and then fail. To investigate what went wrong, you can use the `ec2-describe-conversion-tasks` command to describe the instance. When you receive the FirstBootFailure error message, it means that your virtual disk image was unable to perform one of the following steps:

- Boot up and start Windows.
- Install Amazon EC2 networking and disk drivers.
- Use a DHCP-configured network interface to retrieve an IP address.
- Activate Windows using the Amazon EC2 Windows volume license.

Best Practices for Avoiding First Boot Failures

The following best practices can help you to avoid Windows first boot failures.

Disable anti-virus and anti-spyware software and firewalls

These types of software can prevent installing new Windows services or drivers or prevent unknown binaries from running. Software and firewalls can be re-enabled after importing.

Do not harden your operating system

Security configurations, sometimes called hardening, can prevent unattended installation of Amazon EC2 drivers. There are numerous Windows configuration settings that can prevent import. These settings can be reapplied once imported.

Disable or delete multiple bootable partitions

If your virtual machine boots and requires you to choose which boot partition to use, the import may fail.

Possible Causes of First Boot Failures

This inability of the virtual disk image to boot up and establish network connectivity could be due to any of the following causes.

Topics
- The installation of Windows is not valid on the virtual machine. (p. 295)
- TCP/IP networking and DHCP are not enabled. (p. 295)
- A volume that Windows requires is missing from the virtual machine. (p. 295)
- Windows always boots into System Recovery Options. (p. 295)
The virtual machine was created using a physical-to-virtual (P2V) conversion process. (p. 296)
Windows activation fails. (p. 296)
No bootable partition found. (p. 296)
Linux is not supported on the requested instance. (p. 296)

The installation of Windows is not valid on the virtual machine.

The installation of Windows must be valid before you can successfully import the virtual machine.

Resolution
Do not run System Preparation (Sysprep) before shutting down the EC2 instance. After the instance is imported, you can run Sysprep from the instance before you create an AMI. Importing creates a single instance, so running Sysprep is not necessary.

Ensure that the installation process is fully complete and that Windows boots (without user intervention) to a login prompt.

TCP/IP networking and DHCP are not enabled.

For any Amazon EC2 instance, including those in Amazon VPC, TCP/IP networking and DHCP must be enabled. Within a VPC, you can define an IP address for the instance either before or after importing the instance. Do not set a static IP address before exporting the instance.

Resolution
Ensure that TCP/IP networking is enabled. For more information, see Setting up TCP/IP (Windows Server 2003) or Configuring TCP/IP (Windows Server 2008) at the Microsoft TechNet website.

Ensure that DHCP is enabled. For more information, see What is DHCP at the Microsoft TechNet website.

A volume that Windows requires is missing from the virtual machine.

Importing a VM into Amazon EC2 only imports the boot disk, all other disks must be detached and Windows must able to boot before importing the virtual machine. For example, Active Directory often stores the Active Directory database on the D:\ drive. A domain controller cannot boot if the Active Directory database is missing or inaccessible.

Resolution
Detach any secondary and network disks attached to the Windows VM before exporting.

Move any Active Directory databases from secondary drives or partitions onto the primary Windows partition. For more information, see "Directory Services cannot start" error message when you start your Windows-based or SBS-based domain controller at the Microsoft Support website.

Windows always boots into System Recovery Options.

Windows can boot into System Recovery Options for a variety of reasons, including when Windows is pulled into a virtualized environment from a physical machine, also known as P2V.

Resolution
Ensure that Windows boots to a login prompt before exporting and preparing for import.

Do not import virtualized Windows instances that have come from a physical machine.
The virtual machine was created using a physical-to-virtual (P2V) conversion process.

A P2V conversion occurs when a disk image is created by performing the Windows installation process on a physical machine and then importing a copy of that Windows installation into a VM. VMs that are created as the result of a P2V conversion are not supported by Amazon EC2 VM import. Amazon EC2 VM import only supports Windows images that were natively installed inside the source VM.

Resolution

Install Windows in a virtualized environment and migrate your installed software to that new VM.

Windows activation fails.

During boot, Windows will detect a change of hardware and attempt activation. During the import process we attempt to switch the licensing mechanism in Windows to a volume license provided by Amazon Web Services. However, if the Windows activation process does not succeed, then the import will not succeed.

Resolution

Ensure that the version of Windows you are importing supports volume licensing. Beta or preview versions of Windows might not.

No bootable partition found.

During the import process of a virtual machine, we could not find the boot partition.

Resolution

Ensure that the disk you are importing has the boot partition. We do not support multi-disk import.

Linux is not supported on the requested instance.

Linux import is only supported on specific instance types. You attempted to import an unsupported instance type.

Resolution

Retry using one of the supported instance types.
Instance Lifecycle

This topic describes the lifecycle of an Amazon EC2 instance, from the moment you launch it through its termination. By working with Amazon EC2 to manage your instance, you ensure that your customers have the best possible experience with the applications or sites that you host on your instance.

The following illustration represents the transitions between instance states.

---

Instance Launch

When you launch an instance, it enters the pending state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the running state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance starts to boot, you're billed for each hour or partial hour that you keep the instance running (even if the instance remains idle and you don't connect to it).

For more information, see Launch Your Instance (p. 300) and Connect to Your Instance (p. 308).
**Instance Stop and Start**

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.

When you stop your instance, it enters the **stopping** state, and then the **stopped** state. We don't charge hourly usage or data transfer fees for your instance after you stop it, but we do charge for the storage for any Amazon EBS volumes. While your instance is in the **stopped** state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the **pending** state, and we move the instance to a new host computer. Therefore, when you stop and start your instance, you'll lose any data on the instance store volumes on the previous host computer.

If your instance is running in EC2-Classic, it receives a new private IP address, which means that an Elastic IP address associated with the private IP address is no longer associated with your instance. If your instance is running in EC2-VPC, it retains its private IP address, which means that an Elastic IP address associated with the private IP address or network interface is still associated with your instance.

Each time you transition an instance from **stopped** to **running**, we charge a full instance hour, even if these transitions happen multiple times within a single hour.

For more information, see [Stop and Start Your Instance](p. 319).

**Instance Reboot**

You can reboot your instance using the Amazon EC2 console, the Amazon EC2 CLI, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system; the instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing hour.

For more information, see [Reboot Your Instance](p. 322).

**Instance Retirement**

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware hosting the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS. If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information, see [Instance Retirement](p. 322).
Instance Termination

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to shutting-down or terminated, you stop incurring charges for that instance.

Note that if you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is deleted. You can also describe a terminated instance using the CLI and API. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the InstanceInitiatedShutdownBehavior attribute, which controls whether the instance stops or terminates when you initiate a shutdown from within the instance itself (for example, by using the shutdown command on Linux). The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the DeleteOnTermination attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to preserve volumes that you attach to a running instance and delete volumes that you attach at launch, such as the root volume.

For more information, see Terminate Your Instance (p. 325).

Differences Between Reboot, Stop, and Terminate

Launch Your Instance

An instance is a virtual server in the AWS cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.

When you sign up for AWS, you can get started with Amazon EC2 for free using the AWS Free Usage Tier. You can either leverage the Free Usage Tier to launch and use a micro instance for free for 12 months. If you launch an instance that is not within the Free Usage Tier, you incur the standard Amazon EC2 usage fees for the instance. For more information, see the Amazon EC2 Pricing.

You can launch an instance using the following methods.

After you launch your instance, you can connect to it and use it. To begin, the instance state is pending. When the instance state is running, the instance has started booting. There might be a short time before you can connect to the instance. The instance receives a public DNS name that you can use to contact the instance from the Internet. The instance also receives a private DNS name that other instances within the same Amazon EC2 network (EC2-Classic or EC2-VPC) can use to contact the instance. For more information about connecting to your instance, see Connect to Your Instance (p. 308).

When you are finished with an instance, be sure to terminate it. For more information, see Terminate Your Instance (p. 325).

Launching an Instance

Before you launch your instance, be sure that you are set up. For more information, see Setting Up with Amazon EC2 (p. 19).
Important
When you launch an instance that's not within the AWS Free Usage Tier, you are charged for the time that the instance is running, even if it remains idle.

Topics
• Launching Your Instance from an AMI (p. 301)
• Launching Instances Using an Existing Instance as a Template (p. 305)

Launching Your Instance from an AMI

To launch an instance

1. Open the Amazon EC2 console.

2. In the navigation bar at the top of the screen, the current region is displayed. Click the region's name to select the region for the instance. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. Select the region that meets your needs. For more information, see Resource Locations (p. 606).

3. From the Amazon EC2 console dashboard, click Launch Instance.

4. The Choose an Amazon Machine Image (AMI) page displays a list of basic configurations called Amazon Machine Images (AMIs). An AMI contains all the information needed to create a new instance. For example, an AMI might contain the software required to act as a web server: for example, Linux, Apache, and your website.

Choose the AMI to use and click Select. Start by selecting the type of AMI to use by using these categories on the left pane.

- The Quick Start category displays a selection of popular AMIs to help you get started quickly. To keep things simple, AWS marks the AMIs that are available in the free usage tier with Free tier eligible.
- The My AMIs category displays private AMIs that you own, or private AMIs that have been shared with you.
The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs that you can use to launch your instance. For more information about launching an instance from the AWS Marketplace, see Launching an AWS Marketplace Instance (p. 306).

The Community AMIs option displays public AMIs that AWS community members have made available for others to use.

To filter the list of available AMIs, use the filter options on the left. For example, to view Amazon EBS-backed community AMIs, select the Community AMIs category, select the Amazon Linux check box under Operating system, then select EBS under Root device type.

**Note**
As you choose an AMI, it's important to note whether the AMI is backed by an instance store or by Amazon EBS. For more information, see Storage for the Root Device (p. 50).

5. On the Choose an Instance Type page, select the hardware configuration and size of the instance to launch. Larger instance types have more CPU and memory. For more information about instance families, see Instance Types (p. 97).

To stay within the free tier, select the t1.micro instance, and then click Next: Configure Instance Details.

**Note**
If you are new to AWS and would like to set up an instance quickly and easily, you can click Review and Launch at this point to accept default configuration settings, and launch your instance. For more information, see Getting Started with Amazon EC2 Linux Instances (p. 24).

6. On the Configure Instance Details page, change the following settings as necessary (expand Advanced Details to see all the settings), and then click Next: Add Storage:

- **Number of instances**: Enter the number of instances to launch.
- **Purchasing option**: Select Request Spot Instances to launch a Spot Instance. For more information, see Spot Instances (p. 121).
- **Network**: Your account may support the EC2-Classic and EC2-VPC platforms, or EC2-VPC only. For more information, see Supported Platforms (p. 487).To launch into EC2-Classic, select Launch into EC2-Classic. If your account supports EC2-VPC only, you can launch your instance into your default VPC, which has already been created for you. Regardless of which platform your account supports, you can also launch the instance into a VPC that you have already created, also known as a nondefault VPC.

If you are launching into EC2-Classic:

- **Availability Zone**: Select the Availability Zone to use. To let AWS choose an Availability Zone for you, select No preference.

If you are launching into a VPC:

- **Network**: Select a VPC, or to create a new VPC, click Create new VPC to go to the Amazon VPC console. When you are done, return to the wizard and click Refresh to load your VPC in the list.
- **Subnet**: Select the subnet into which to launch your instance. If your account is EC2-VPC only, select No preference to let AWS choose a default subnet in any Availability Zone. To create a new subnet, click Create new subnet to go to the Amazon VPC console. When you are done, return to the wizard and click Refresh to load your subnet in the list.
- **Public IP**: Select this check box to request that your instance receives a public IP address. For more information about public IP addressing, see Amazon EC2 Instance IP Addressing (p. 489).
- **IAM role**: If applicable, select an AWS Identity and Access Management (IAM) role to associate with the instance. For more information, see IAM Roles for Amazon EC2 (p. 477).
- **Shutdown behavior**: Select whether the instance should stop or terminate when shut down. For more information, see Changing the Instance Initiated Shutdown Behavior (p. 327).
• **Enable termination protection**: Select this check box to prevent accidental termination. For more information, see *Enabling Termination Protection for an Instance* (p. 326).

• **Monitoring**: Select this check box to enable detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see *Monitoring Your Instances with CloudWatch* (p. 364).

• **EBS-Optimized instance**: An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, select this check box to enable it. Additional charges apply. For more information, see *Amazon EBS-Optimized Instances* (p. 114).

• **Tenancy**: If you are launching your instance into a VPC, you can select **Dedicated tenancy** to run your instance on isolated, dedicated hardware. Additional charges apply. For more information, see *Dedicated Instances* in the *Amazon Virtual Private Cloud User Guide*.

• **Network interfaces**: If you are launching an instance into a VPC and you did not select **No Preference** for your subnet, you can specify up to two network interfaces in the wizard. Click **Add IP** to assign more than one IP address to the selected interface. For more information about network interfaces, see *Elastic Network Interfaces (ENI)* (p. 503). If you selected the **Public IP** check box above, you can only assign a public IP address to a single, new network interface with the device index of eth0. For more information, see *Assigning a Public IP Address* (p. 493).

• **Kernel ID**: Select **Use default** unless you want to use a specific kernel.

• **RAM disk ID**: Select **Use default** unless you want to use a specific RAM disk. If you have selected a kernel, you may need to select a specific RAM disk with the drivers to support it.

• **Placement group**: A placement group is a logical grouping for your cluster instances. Select an existing placement group, or create a new one. This option is only available if you’ve selected an instance type that supports placement groups. For more information, see *Placement Groups* (p. 115).

• **User data**: You can specify user data to configure an instance during launch, or to run a configuration script. To attach a file, select the **As file** option and browse for the file to attach.

7. On the **Add Storage** page, you can specify volumes to attach to the instance besides the volumes specified by the AMI (such as the root device volume). You can change the following options, then click **Next: Tag Instance** when done:

   • **Type**: Select instance store or Amazon EBS volumes to associate with your instance. The type of volume available in the list depends on the instance type you’ve chosen. For more information, see *Amazon EC2 Instance Store* (p. 582) and *Amazon EBS Volumes* (p. 524).

   • **Device**: Select from the list of available device names for the volume.

   • **Snapshot**: Enter the name or ID of the snapshot from which to restore a volume. You can also search for public snapshots by typing text into the **Snapshot** field. Snapshot descriptions are case-sensitive.

   • **Size**: For Amazon EBS-backed volumes, you can specify a storage size. Note that even if you have selected an AMI and instance that are eligible for the free usage tier, you need to keep under 30 GB of total storage to stay within the free usage tier.

   **Note**

   If you increase the size of your root volume at this point (or any other volume created from a snapshot), you need to extend the file system on that volume in order to use the extra space. For more information about extending your file system after your instance has launched, see *Expanding the Storage Space of a Volume* (p. 548).

   • **Volume Type**: For Amazon EBS volumes, select either a Standard or Provisioned IOPS volume. For more information, see *Amazon EBS Volume Types* (p. 525).

   • **IOPS**: If you have selected a Provisioned IOPS volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.

   • **Delete on Termination**: For Amazon EBS volumes, select this check box to delete the volume when the instance is terminated. For more information, see *Preserving Amazon EBS Volumes on Instance Termination* (p. 328).
8. On the Tag Instance page, specify tags for the instance by providing key and value combinations. Click Create Tag to add more than one tag to your resource. Click Next: Configure Security Group when you are done.

For more information about tags, see Tagging Your Amazon EC2 Resources (p. 610).

9. On the Configure Security Group page, the wizard automatically defines the launch-wizard-x security group to allow you to connect to your instance.

A security group defines firewall rules for your instances. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. The launch-wizard-x security group automatically allows traffic on either SSH (port 22) for Linux instances, or RDP (port 3389) for Windows instances.

Caution
The launch-wizard-x security group enables all IP addresses (0.0.0.0/0) to access your instance over the specified ports. This is acceptable for this short exercise, but it's unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

You can modify the default rule in the launch-wizard-x security group to suit your needs. For example, if you want to use your instance as a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow Internet traffic to reach your instance.

Select My IP from the Source list to let the wizard add your computer’s public IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers. Click Add Rule to add more rules to the group.

You can also select the Select an existing security group option to use one of your existing security groups, for example, the one you created when getting set up. You can’t edit an existing group’s rules, but you can copy its rules into a new group clicking the Copy to new link for that group.

For more information about security groups, see Amazon EC2 Security Groups (p. 440).

When you are done, click Review and Launch.

10. On the Review Instance Launch page, check the details of your instance, and make any necessary changes by clicking the appropriate Edit link.

When you are ready, click Launch.

11. In the Select an existing key pair or create a new key pair dialog box, you can choose an existing key pair, or create a new one. For example, select Choose an existing key pair, then select the key pair you created when getting set up.

To launch your instance, select the acknowledgment check box, then click Launch Instances.

For more information about creating key pairs, see Amazon EC2 Key Pairs (p. 433).

Important
We recommend against selecting the Proceed without key pair option. If you launch an instance without a key pair, you won’t be able to connect to it. This option is used only when you are creating your own AMI and don’t need to connect to the instance.

12. If the instance state immediately goes to terminated instead of running, you can get information about why the instance didn’t launch. For more information, see What To Do If An Instance Immediately Terminates (p. 630).
Launching Instances Using an Existing Instance as a Template

The Amazon EC2 console provides a **Launch More Like This** wizard option that enables you to use a current instance as a template for launching other instances. This option automatically populates the Amazon EC2 launch wizard with certain configuration details from the selected instance.

**Note**

The **Launch More Like This** wizard option does not clone your selected instance; it only replicates some configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI.

The following configuration details are copied from the selected instance into the launch wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Tags associated with the instance, if applicable
- Kernel ID and RAM disk ID, if applicable
- IAM role associated with the instance, if applicable
- Security group associated with the instance
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Amazon EBS-optimization setting (true or false)

The following configuration details are not copied from your selected instance; instead, the wizard applies their default settings or behavior:

- Storage: The default storage configuration is determined by the AMI and the instance type.
- Public IP address: The option to assign a public IP address to your instance is enabled by default when launching into a default subnet.
- Termination protection: Disabled by default.
- Shutdown behavior: Set to ‘stop’ by default.
- User data: None by default.

To use your current instance as a template

1. On the Instances page, select the instance you want to use.
2. Click **Actions**, and select **Launch More Like This**.
3. The launch wizard opens on the **Review Instance Launch** page. You can check the details of your instance, and make any necessary changes by clicking the appropriate **Edit** link.

When you are ready, click **Launch** to select a key pair and launch your instance.

Launching an Instance from a Backup

With an Amazon EBS-backed instance, you can back up the root device volume of the instance by creating a snapshot. When you have a snapshot of the root device volume of an instance, you can terminate that instance and then later launch a new instance from the snapshot. This can be useful if you don't have the original AMI that you launched an instance from, but you need to be able to launch an instance using the same image.
Important
At this time, although you can create a Windows AMI from a snapshot, you can't launch an instance from the AMI.

Use the following procedure to create an AMI from the root volume of your instance. If you prefer, you can use the `ec2-register` command instead.

To create an AMI from your root volume

1. Open the Amazon EC2 console.
2. In the navigation pane, under Elastic Block Store, click Snapshots.
3. Click Create Snapshot.
4. In the Volumes field, start typing the name or ID of the root volume, and then select it from the list of options.
5. Select the snapshot that you just created, and then select Create Image from the Actions list.
6. In the Create Image from EBS Snapshot dialog box, complete the fields to create your AMI, then click Create. Be sure to do the following:
   - Select the architecture from the Architecture list (i386 for 32-bit or x86_64 for 64-bit).
   - Select the AKI from the Kernel ID list. If you select the default AKI or don't select an AKI, you'll be required to specify an AKI every time you launch an instance. In addition, your instance may fail the health check because the default AKI is incompatible with the instance.
7. In the navigation pane, select AMIs.
8. Select the AMI that you just created, and then click Launch. Follow the wizard to launch your instance. For more information about how to configure each step in the wizard, see Launching an Instance (p. 300).

Launching an AWS Marketplace Instance

You can subscribe to an AWS Marketplace product and launch an instance from the product's AMI using the Amazon EC2 launch wizard. For more information about paid AMIs, see Paid AMIs (p. 64). To cancel your subscription after launch, you first have to terminate all instances running from it. For more information, see Managing Your AWS Marketplace Subscriptions (p. 68).

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Amazon EC2 dashboard, click Launch Instance.
3. On the Choose an Amazon Machine Image (AMI) page, select the AWS Marketplace category on the left. Find a suitable AMI by browsing the categories, or using the search functionality. Click Select to choose your product.
4. A dialog displays an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, click Continue.
   
   **Note**
   
   You are not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type, as you will be prompted to select an instance type on the next page of the wizard.
5. On the Choose an Instance Type page, select the hardware configuration and size of the instance to launch. When you're done, click Next: Configure Instance Details.
6. On the next pages of the wizard, you can configure your instance, add storage, and add tags. For more information about the different options you can configure, see Launching an Instance (p. 300). Click Next until you reach the Configure Security Group page.

The wizard creates a new security group according to the vendor’s specifications for the product. The security group may include rules that allow all IP addresses (0.0.0.0/0) access on SSH (port 22) or RDP (port 3389). We recommend that you adjust these rules to allow only a specific IP address or range of addresses to access your instance over those specific ports.

When you are ready, click Review and Launch.

7. On the Review Instance Launch page, check the details of the AMI from which you’re about to launch the instance, as well as the other configuration details you set up in the wizard. When you’re ready, click Launch to choose or create a key pair, and launch your instance.

8. Depending on the product you’ve subscribed to, the instance may take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, click View Instances to go to the Instances page.

   **Note**
   You are charged the subscription price as long as your instance is running, even if it is idle. If your instance is stopped, you may still be charged for storage.

9. When your instance is in the running state, you can connect to it. To do this, select your instance in the list and click Connect. Follow the instructions in the dialog. For more information about connecting to your instance, see Connect to Your Instance (p. 308).

   **Important**
   Check the vendor's usage instructions carefully, as you may need to use a specific user name to log in to the instance. For more information about accessing your subscription details, see Managing Your AWS Marketplace Subscriptions (p. 68).

### Launching an AWS Marketplace AMI Instance Using the API and CLI

To launch instances from AWS Marketplace products using the API or command line tools, first ensure that you are subscribed to the product. You can then launch an instance with the product’s AMI ID using the following methods:

**Connecting to Your Linux/Unix Instances Using SSH**

After you launch your instance, you can connect to it and use it the way that you’d use a computer sitting in front of you.

If you receive an error while attempting to connect to your instance, see Troubleshooting Connecting to Your Instance.

The following instructions explain how to connect to your instance using an SSH client.

**Topics**
- Prerequisites (p. 308)
- Connecting to Your Linux/Unix Instance (p. 309)
- Transferring Files to Linux/Unix Instances from Linux/Unix with SCP (p. 310)

**Prerequisites**

- **Install an SSH client**
  Your Linux computer mostly includes an SSH client by default. You can check for an SSH client by typing `ssh` at the command line. If your computer doesn’t recognize the command, the OpenSSH project provides a free implementation of the full suite of SSH tools. For more information, see http://www.openssh.org.

- **Install the Amazon EC2 CLI Tools**
  (Optional) If you’re using a public AMI from a third party, use the `ec2-get-console-output` command to verify the fingerprint.

- **Get the ID of the instance**
  You can get the ID of your instance using the Amazon EC2 console (from the Instance ID column). If you prefer, you can use the `ec2-describe-instances` command.

- **Get the public DNS name of the instance**
You can get the public DNS for your instance using the Amazon EC2 console (check the Public DNS column; if this column is hidden, click the Show/Hide icon and select Public DNS). If you prefer, you can use the `ec2-describe-instances` command.

- **Locate the private key**
  You'll need the fully-qualified path of the `.pem` file for the key pair that you specified when you launched the instance.

- **Enable inbound SSH traffic from your IP address to your instance**
  Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Authorizing Network Access to Your Instances.

### Connecting to Your Linux/Unix Instance

To connect to your instance using SSH

1. (Optional) If you've launched a public AMI from a third party, run the `ec2-get-console-output` command on your local system (not on the instance), and locate the SSH HOST KEY FINGERPRINTS section. Note the fingerprints (for example, 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f) so that you can compare them to the fingerprints of the instance.

   ```
   ec2-get-console-output instance_id
   ```

2. In a command line shell, change directories to the location of the private key file that you created when you launched the instance.

3. Use the `chmod` command to make sure your private key file isn't publicly viewable. For example, if the name of your private key file is `my-key-pair.pem`, you would use the following command:

   ```
   chmod 400 my-key-pair.pem
   ```

4. Use the `ssh` command to connect to the instance. You'll specify the private key `.pem` file and `user_name@public_dns_name`. For Amazon Linux, the default user name is `ec2-user`. For RHEL5, the user name is often `root` but might be `ec2-user`. For Ubuntu, the user name is `ubuntu`. For SUSE Linux, the user name is `root`. Otherwise, check with your AMI provider.

   ```
   ssh -i my-key-pair.pem ec2-user@ec2-198-51-100-1.compute-1.amazonaws.com
   ```

   You'll see a response like the following.

   ```
   The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
   Are you sure you want to continue connecting (yes/no)?
   ```

5. (Optional) If you've launched a public AMI, verify that the fingerprint in the security alert matches the fingerprint that you obtained in step 1. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

6. Enter `yes`.

   You'll see a response like the following.
Transferring Files to Linux/Unix Instances from Linux/Unix with SCP

One way to transfer files between your local computer and a Linux/Unix instance is to use Secure Copy (SCP). This section describes how to transfer files with SCP. The procedure is very similar to the procedure for connecting to an instance with SSH.

Prerequisites

- **Install an SCP client**
  Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn’t, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, go to [http://www.openssh.org](http://www.openssh.org).

- **Get the ID of the instance**
  You can get the ID of your instance using the Amazon EC2 console (from the **Instance ID** column). If you prefer, you can use the `ec2-describe-instances` command.

- **Get the public DNS name of the instance**
  You can get the public DNS for your instance using the Amazon EC2 console (check the **Public DNS** column; if this column is hidden, click the **Show/Hide** icon and select **Public DNS**). If you prefer, you can use the `ec2-describe-instances` command.

- **Locate the private key**
  You’ll need the fully-qualified path of the `.pem` file for the key pair that you specified when you launched the instance.

- **Enable inbound SSH traffic from your IP address to your instance**
  Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see **Authorizing Network Access to Your Instances**.

The following procedure steps you through using SCP to transfer a file. If you’ve already connected to the instance with SSH and have verified its fingerprints, you can start with the step that contains the SCP command (step 4).

To use SCP to transfer a file

1. (Optional) If you’ve launched a public AMI from a third party, run the `ec2-get-console-output` command on your local system (not on the instance), and locate the **SSH HOST KEY FINGERPRINTS** section. Note the fingerprints (for example, 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f1:6f) so that you can compare them to the fingerprints of the instance.

   `ec2-get-console-output instance_id`

2. In a command shell, change directories to the location of the private key file that you specified when you launched the instance.

3. Use the `chmod` command to make sure your private key file isn’t publicly viewable. For example, if the name of your private key file is `my-key-pair.pem`, you would use the following command:
chmod 400 my-key-pair.pem

4. Transfer a file to your instance using the instance’s public DNS name. For example, if the name of the private key file is my-key-pair, the file to transfer is SampleFile.txt, and the public DNS name of the instance is ec2-198-51-100-1.compute-1.amazonaws.com, use the following command to copy the file to the ec2-user home directory.

```bash
scp -i my-key-pair.pem SampleFile.txt ec2-user@ec2-198-51-100-1.compute-1.amazonaws.com:~
```

**Tip**
For Amazon Linux, the default user name is ec2-user. For RHEL5, the user name is often root but might be ec2-user. For Ubuntu, the user name is ubuntu. For SUSE Linux, the user name is root. Otherwise, check with your AMI provider.

You’ll see a response like the following.

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
Are you sure you want to continue connecting (yes/no)?
```

5. (Optional) If you’ve launched a public AMI, verify that the fingerprint in the security alert matches the fingerprint that you obtained in step 1. If these fingerprints don’t match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

6. Enter yes.

You’ll see a response like the following.

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
Sending file modes: C0644 20 SampleFile.txt
Sink: C0644 20 SampleFile.txt
SampleFile.txt                                100%   20     0.0KB/s   00:00
```

To transfer files in the other direction (from your Amazon EC2 instance to your local computer), simply reverse the order of the host parameters. For example, to transfer the SampleFile.txt file from your EC2 instance back to the home directory on your local computer as SampleFile2.txt, use the following command on your local computer.

```bash
scp -i my-key-pair.pem ec2-user@ec2-198-51-100-1.compute-1.amazonaws.com:~/Sample File.txt ~/SampleFile2.txt
```
Connecting to Linux/Unix Instances from Windows Using PuTTY

After you launch your instance, you can connect to it and use it the way that you’d use a computer sitting in front of you.

If you receive an error while attempting to connect to your instance, see Troubleshooting Connecting to Your Instance.

The following instructions explain how to connect to your instance using PuTTY, a free SSH client for Windows.

Topics
- Prerequisites (p. 312)
- Converting Your Private Key Using PuTTYgen (p. 312)
- Starting a PuTTY Session (p. 313)
- Transferring Files to Your Instance with the PuTTY Secure Copy Client (p. 315)
- Transferring Files to Your Instance with WinSCP (p. 315)

Prerequisites
- Install PuTTY
  Download and install PuTTY from the PuTTY download page. Be sure to install the entire suite.

- Get the ID of the instance
  You can get the ID of your instance using the Amazon EC2 console (from the Instance ID column). If you prefer, you can use the ec2-describe-instances command.

- Get the public DNS name of the instance
  You can get the public DNS for your instance using the Amazon EC2 console (check the Public DNS column; if this column is hidden, click the Show/Hide icon and select Public DNS). If you prefer, you can use the ec2-describe-instances command.

- Locate the private key
  You’ll need the fully-qualified path of the .pem file for the key pair that you specified when you launched the instance.

- Enable inbound SSH traffic from your IP address to your instance
  Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Authorizing Network Access to Your Instances.

Converting Your Private Key Using PuTTYgen

PuTTY does not natively support the private key format (.pem) generated by Amazon EC2. PuTTY has a tool named PuTTYgen, which can convert keys to the required PuTTY format (.ppk). You must convert your private key into this format (.ppk) before attempting to connect to your instance using PuTTY.

To convert your private key
1. Start PuTTYgen (for example, from the Start menu, click All Programs > PuTTY > PuTTYgen).
2. Under Type of key to generate, select SSH-2 RSA.
3. Click **Load**. By default, PuTTYgen displays only files with the extension .ppk. To locate your .pem file, select the option to display files of all types.

4. Select your .pem file and click **Open**. Click **OK** to dismiss the confirmation dialog box.

5. Click **Save private key** to save the key in the format that PuTTY can use. PuTTYgen displays a warning about saving the key without a passphrase. Click **Yes**.

   **Note**
   A passphrase on a private key is an extra layer of protection, so even if your private key is discovered, it can't be used without the passphrase. The downside to using a passphrase is that it makes automation harder because human intervention is needed to log on to an instance, or copy files to an instance.

6. Specify the same name for the key that you used for the key pair (for example, my-key-pair). PuTTY automatically adds the .ppk file extension.

   Your private key is now in the correct format for use with PuTTY. You can now connect to your instance using PuTTY's SSH client.

**Starting a PuTTY Session**

**To start a PuTTY session**

1. (Optional) If you've launched a public AMI from a third party, run the `ec2-get-console-output` command on your local system (not on the instance), and locate the SSH HOST KEY FINGERPRINTS section. Note the fingerprints (for example, 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f) so that you can compare them to the fingerprints of the instance.

   ```
   C:\> ec2-get-console-output instance_id
   ```

2. Start PuTTY (from the **Start** menu, click **All Programs > PuTTY > PuTTY**).

3. In the Category pane, select **Session** and complete the following fields:
   a. In the **Host Name** box, enter `user_name@public_dns_name`. Be sure to specify the appropriate user name for your AMI. For example:
      - For an Amazon Linux AMI, the user name is `ec2-user`.
      - For a RHEL5 AMI, the user name is often `root` but might be `ec2-user`.
      - For an Ubuntu AMI, the user name is `ubuntu`.
      - Otherwise, check with your AMI provider.

   b. Under **Connection type**, select **SSH**.

   c. Ensure that **Port** is 22.
4. In the Category pane, expand Connection, expand SSH, and then select Auth. Complete the following:
   a. Click Browse.
   b. Select the .ppk file that you generated for your key pair, and then click Open.
   c. (Optional) If you plan to start this session again later, you can save the session information for future use. Select Session in the Category tree, enter a name for the session in Saved Sessions, and then click Save.
   d. Click Open to start the PuTTY session.

5. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host you are connecting to.

6. (Optional) If you've launched a public AMI, verify that the fingerprint in the security alert matches the fingerprint that you obtained in step 1. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
7. Click Yes. A window opens and you are connected to your instance.

   Note
   If you specified a passphrase when you converted your private key to PuTTY’s format, you must provide that passphrase when you log in to the instance.

Transferring Files to Your Instance with the PuTTY Secure Copy Client

The PuTTY Secure Copy client (PSCP) is a command-line tool that you can use to transfer files between your Windows computer and your Linux/Unix instance. If you prefer a graphical user interface (GUI), you can use an open source GUI tool named WinSCP. For more information, see Transferring Files to Your Instance with WinSCP (p. 315).

To use PSCP, you’ll need the private key you generated in Converting Your Private Key Using PuTTYgen (p. 312). You’ll also need the public DNS address of your Linux/Unix instance.

The following example transfers the file Sample_file.txt from a Windows computer to the /usr/local directory on a Linux/Unix instance:

    C:\> pscp -i C:\Keys\my-key-pair.ppk C:\Sample_file.txt user_name@public_dns:/usr/local/Sample_file.txt

Transferring Files to Your Instance with WinSCP

WinSCP is a GUI-based file manager for Windows that allows you to upload and transfer files to a remote computer using the SFTP, SCP, FTP, and FTPS protocols. WinSCP allows you to drag and drop files from your Windows machine to your Linux instance or synchronize entire directory structures between the two systems.

To use WinSCP, you’ll need the private key you generated in Converting Your Private Key Using PuTTYgen (p. 312). You’ll also need the public DNS address of your Linux/Unix instance.

1. Download and install WinSCP from http://winscp.net/eng/download.php. For most users, the default installation options are OK.
2. Start WinSCP.
3. At the WinSCP login screen, for Host name, enter the public DNS address for your instance.
4. For User name, enter the default user name for your AMI. For Amazon Linux AMIs, the user name is ec2-user. For Red Hat AMIs the user name is root, and for Ubuntu AMIs the user name is ubuntu.
5. For Private key, enter the path to your private key, or click the "..." button to browse for the file.

   Note
   WinSCP requires a PuTTY private key file (.ppk). You can convert a .pem security key file to the .ppk format using PuTTYgen. For more information, see Converting Your Private Key Using PuTTYgen (p. 312).
6. (Optional) In the left panel, click Directories, and then, for Remote directory, enter the path for the directory you want to add files to.
7. Click Login to connect, and click Yes to add the host fingerprint to the host cache.
8. After the connection is established, in the connection window your Linux instance is on the right and your local machine is on the left. You can drag and drop files directly into the remote file system from your local machine. For more information on WinSCP, see the project documentation at http://winscp.net/eng/docs/start.

Connecting to Your Instance from Your Web Browser Using MindTerm

After you launch your instance, you can connect to it and use it the way that you’d use a computer sitting in front of you.

If you receive an error while attempting to connect to your instance, see Troubleshooting Connecting to Your Instance.

The following instructions explain how to connect to your instance using MindTerm through the Amazon EC2 console.

Prerequisites

- **Install Java**
  
  Your Linux computer most likely includes Java. If not, see How do I enable Java in my web browser? On a Windows or Mac client, you must run your browser using administrator credentials. For Linux, additional steps may be required if you are not logged in as root.

- **Enable Java in your browser**
  
  For instructions, see http://java.com/en/download/help/enable_browser.xml.

- **Locate the private key**
  
  You’ll need the fully-qualified path of the .pem file for the key pair that you specified when you launched the instance.

- **Enable inbound SSH traffic from your IP address to your instance**
Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. For more information, see Authorizing Network Access to Your Instances.

**Starting MindTerm**

To connect to your instance using a web browser with MindTerm

1. In the Amazon EC2 console, click **Instances** in the navigation pane.
2. Select the instance, and then click **Connect**.
3. Click **A Java SSH client directly from my browser (Java required)**.
4. Amazon EC2 automatically detects the public DNS name of your instance and the name of the key pair that you specified when you launched the instance. Complete the following, and then click **Launch SSH Client**.
   a. In **User name**, enter the user name to log in to your instance.
   
   Tip
   For Amazon Linux, the default user name is `ec2-user`. For RHEL5, the user name is often `root` but might be `ec2-user`. For Ubuntu, the user name is `ubuntu`. For SUSE Linux, the user name is `root`. Otherwise, check with your AMI provider.
   b. In **Private key path**, enter the fully-qualified path to your private key (.pem) file.
   c. (Optional) Click **Store in browser cache** to store the location of the private key in your browser cache. This enables Amazon EC2 to detect the location of the private key in subsequent browser sessions, until you clear your browser's cache.
   
5. If necessary, click **Yes** to trust the certificate.
6. Click **Run** to run the MindTerm client.
7. If you accept the license agreement, click **Accept**.
8. If this is your first time running MindTerm, a series of dialog boxes asks you to confirm setup for your home directory and other settings. Confirm these settings. A window opens and you are connected to your instance.

**Connecting to Windows Instances Using RDP**

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

If you receive an error while attempting to connect to your instance, see Troubleshooting Windows Instances in the *Amazon Elastic Compute Cloud Microsoft Windows Guide*.

The following instructions explain how to connect to your instance using an RDP client.

**Topics**
- Prerequisites (p. 317)
- Connect to Your Windows Instance (p. 318)
- Transfer Files to Windows Server Instances from Windows (p. 319)

**Prerequisites**
- Install an RDP client
Your Windows computer includes an RDP client by default. You can check for an RDP client by typing `mstsc` at a Command Prompt window. If your computer doesn't recognize this command, see the Microsoft Windows home page and search for the download for Remote Desktop Connection. For Mac OS X, you can use Microsoft's Remote Desktop Client. For Linux/Unix, you can use `rdesktop`.

- **Get the ID of the instance**
  You can get the ID of your instance using the Amazon EC2 console (from the **Instance ID** column). If you prefer, you can use the `ec2-describe-instances` command.

- **Get the public DNS name of the instance**
  You can get the public DNS for your instance using the Amazon EC2 console (check the **Public DNS** column; if this column is hidden, click the **Show/Hide** icon and select **Public DNS**). If you prefer, you can use the `ec2-describe-instances` command.

- **Locate the private key**
  You'll need the fully-qualified path of the `.pem` file for the key pair that you specified when you launched the instance.

- **Enable inbound RDP traffic from your IP address to your instance**
  Ensure that the security group associated with your instance allows incoming RDP traffic from your IP address. For more information, see **Authorizing Network Access to Your Instances**.

- **For the best experience using Internet Explorer, run the latest version.**

### Connect to Your Windows Instance

To connect to a Windows instance, you must retrieve the initial administrator password and then specify this password when you connect to your instance using Remote Desktop.

*Note*

Windows instances are limited to two simultaneous remote connections at one time. If you attempt a third connection, an error will occur. For more information, see **Configure the Number of Simultaneous Remote Connections Allowed for a Connection**.

**To connect to your Windows instance**

1. In the Amazon EC2 console, select the instance, and then click **Connect**.
2. In the **Connect To Your Instance** dialog box, click **Get Password** (it will take a few minutes after the instance is launched before the password is available).
3. Click **Browse** and navigate to the private key file you created when you launched the instance. Select the file and click **Open** to copy the entire contents of the file into contents box.
4. Click **Decrypt Password**. The console displays the default administrator password for the instance in the **Connect To Your Instance** dialog box, replacing the link to **Get Password** shown previously with the actual password.
5. Record the default administrator password, or copy it to the clipboard. You need this password to connect to the instance.
6. Click **Download Remote Desktop File**. Your browser prompts you to either open or save the `.rdp` file. Either option is fine. When you have finished, you can click **Close** to dismiss the **Connect To Your Instance** dialog box.
7. If you opened the `.rdp` file, you'll see the **Remote Desktop Connection** dialog box. If you saved the `.rdp` file, navigate to your downloads directory, and double-click the `.rdp` file to display the dialog box. You may get a warning that the publisher of the remote connection is unknown. Click **Connect** to connect to your instance. You may get a warning that the security certificate could not be authenticated. Click **Yes** to continue.
8. Log in to the instance as prompted, using the default **Administrator** account and the default administrator password that you recorded or copied previously.
After you connect, we recommend that you do the following:

- Change the Administrator password from the default value. You change the password while logged on to the instance itself, just as you would on any other Windows Server.
- Create another user account with administrator privileges on the instance. Another account with administrator privileges is a safeguard if you forget the Administrator password or have a problem with the Administrator account.

**Transfer Files to Windows Server Instances from Windows**

You can work with your instance the same way you would work with any Windows server. For example, you can transfer files between an Amazon EC2 Windows instance and your local Windows computer using the local file sharing feature of Windows Remote Desktop. If you enable this option in your Windows Remote Desktop Connection software, you can access your local files from your Amazon EC2 Windows instances. You can access local files on hard disk drives, DVD drives, portable media drives, and mapped network drives. For information about this feature, go to the Microsoft Support website or go to The most useful feature of Remote Desktop I never knew about on the MSDN Blogs website.

**Stop and Start Your Instance**

You can stop and restart your instance if it has an Amazon EBS volume as its root device. The instance retains its instance ID, but can change as described in the Overview section.

When you stop an instance, we shut it down. We don't charge hourly usage for a stopped instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes. Each time you start a stopped instance we charge a full instance hour, even if you make this transition multiple times within a single hour. If you have stopped your Amazon EBS-backed instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see Troubleshooting Stopping Your Instance (p. 636).

While the instance is stopped, you can treat its root volume like any other volume, and modify it (for example, repair file system problems or update software). You just detach the volume from the stopped instance, attach it to a running instance, make your changes, detach it from the running instance, and then reattach it to the stopped instance. Make sure that you reattach it using the storage device name that's specified as the root device in the block device mapping for the instance.

If you decide that you no longer need an instance, you can terminate it. As soon as the state of an instance changes to shutting-down or terminated, we stop charging for that instance. For more information, see Terminate Your Instance (p. 325).

**Overview**

You can only stop an Amazon EBS-backed instance. To verify the root device type of your instance, describe the instance and check whether the device type of its root volume is ebs (Amazon EBS-backed instance) or instance store (instance store-backed instance).

When you stop a running instance, the following happens:

- The instance performs a normal shutdown and stops running; its status changes to stopping and then stopped.
- Any Amazon EBS volumes remain attached to the instance, and their data persists.
- Any data stored in the RAM of the host computer or the instance store volumes of the host computer is gone.
• EC2-Classic: We release the public and private IP addresses for the instance when you stop the instance, and assign new ones when you restart it.

EC2-VPC: The instance retains its private IP addresses when stopped and restarted. We release the public IP address and assign a new one when you restart it.

• EC2-Classic: We disassociate any Elastic IP address that's associated with the instance. You're charged for Elastic IP addresses that aren't associated with an instance. When you restart the instance, you must associate the Elastic IP address with the instance; we don't do this automatically.

EC2-VPC: The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses associated with a stopped instance.

• When you stop and restart a Windows instance, by default, we change the instance host name to match the new IP address and initiate a reboot. By default, we also change the drive letters for any attached Amazon EBS volumes. For more information about these defaults and how you can change them, see Configuring a Windows Instance Using the EC2Config Service in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

• If you've registered the instance with a load balancer, it's likely that the load balancer won't be able to route traffic to your instance after you've stopped and restarted it. You must de-register the instance from the load balancer after stopping the instance, and then re-register after starting the instance. For more information, see De-Registering and Registering Amazon EC2 Instances in the Elastic Load Balancing Developer Guide.

You can modify the following attributes of an instance only when it is stopped:

• Instance type
• User data
• Kernel
• RAM disk

If you try to modify these attributes while the instance is running, Amazon EC2 returns the IncorrectInstanceState error.

### Stopping and Starting Your Instances

You can stop and start your Amazon EBS-backed instance using the console or the command line.

#### To stop and start an Amazon EBS-backed instance using the console

1. In the navigation pane, click **Instances**, and select the instance.
2. [EC2-Classic] If the instance has an associated Elastic IP address, write down the Elastic IP address and the instance ID shown in the details pane.
3. Click **Actions**, and then click **Stop**. If **Stop** is disabled, either the instance is already stopped or its root device is an instance store volume.
4. In the confirmation dialog box, click **Yes, Stop**. It can take a few minutes for the instance to stop.

   [EC2-Classic] When the instance state becomes **stopped**, the Elastic IP, Public DNS, Private DNS, and Private IPs fields in the details pane are blank to indicate that the old values are no longer associated with the instance.

5. While your instance is stopped, you can modify certain instance attributes. For more information, see Modifying a Stopped Instance (p. 321).
6. To restart the stopped instance, select the instance, click **Actions**, and then click **Start**.
7. In the confirmation dialog box, click **Yes, Start**. It can take a few minutes for the instance to enter the running state.
When the instance state becomes running, the Public DNS, Private DNS, and Private IPs fields in the details pane contain the new values that we assigned to the instance.

8. If your instance had an associated Elastic IP address, you must reassociate it as follows:
   a. In the navigation pane, click Elastic IPs.
   b. Select the Elastic IP address that you wrote down before you stopped the instance.
   c. Click Associate Address.
   d. Select the instance ID that you wrote down before you stopped the instance, and then click Associate.

To stop and start an Amazon EBS-backed instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- stop-instances and start-instances (AWS CLI)
- ec2-stop-instances and ec2-start-instances (Amazon EC2 CLI)
- Stop-EC2Instance and Start-EC2Instance (AWS Tools for Windows PowerShell)

Modifying a Stopped Instance

You can change the instance type and user data attributes using the AWS Management Console or the command line interface. You can't use the AWS Management Console to modify the kernel or RAM disk attributes.

To change the instance type for a stopped instance using the console

1. In the navigation pane, click Instances.
2. Select the stopped instance, click Actions, and then click Change Instance Type.
3. In the Change Instance Type dialog box, in the Instance Type list, select the type of instance you need, and then click Apply.
   
   For more information, see Resizing Your Instance (p. 118).

To change the user data for a stopped instance using the console

1. In the navigation pane, click Instances.
2. Select the stopped instance, click Actions, and then click View/Change User Data.
3. In the View/Change User Data dialog box, update the user data, and then click Save. Note that you can't change the user data if the instance is running, but you can view it.

To modify an instance attribute using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- modify-instance-attribute (AWS CLI)
- ec2-modify-instance-attribute (Amazon EC2 CLI)
- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)
Reboot Your Instance

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing hour, unlike stopping and restarting your instance.

We might schedule your instance for a reboot for necessary maintenance, such as to apply updates that require a reboot. No action is required on your part; we recommend that you wait for the reboot to occur within its scheduled window. For more information, see Monitoring Events for Your Instances (p. 361).

We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

To reboot an instance using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click Instances.
3. Select the instance, click Actions, and then click Reboot.
4. Click Yes, Reboot when prompted for confirmation.

To reboot an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- reboot-instances (AWS CLI)
- ec2-reboot-instances (Amazon EC2 CLI)
- Restart-EC2Instance (AWS Tools for Windows PowerShell)

Instance Retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware hosting the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS. If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware. If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

Topics

- Identifying Instances Scheduled for Retirement (p. 322)
- Working with Instances Scheduled for Retirement (p. 323)

For more information about types of instance events, see Monitoring Events for Your Instances (p. 361).

Identifying Instances Scheduled for Retirement

If your instance is scheduled for retirement, you’ll receive an email prior to the event with the instance ID and retirement date. This email is sent to the address that’s associated with your account; the same email address that you use to log in to the AWS Management Console. If you use an email account that you
do not check regularly, then you can use the Amazon EC2 console or the command line to determine if any of your instances are scheduled for retirement.

To identify instances scheduled for retirement using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click **EC2 Dashboard**. Under **Scheduled Events**, you can see the events associated with your Amazon EC2 instances and volumes, organized by region.

   ![Scheduled Events](image)

   US East (N. Virginia):

   1 instances have scheduled events

3. If you have an instance with a scheduled event listed, click its link below the region name to go to the **Events** page.
4. The **Events** page lists all resources with events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance retirement** from the second filter list.
5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

To identify instances scheduled for retirement using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-instance-status` (AWS CLI)
- `ec2-describe-instance-status` (Amazon EC2 CLI)
- `Get-EC2InstanceStatus` (AWS Tools for Windows PowerShell)

Working with Instances Scheduled for Retirement

There are a number of actions available to you when your instance is scheduled for retirement. The action you take depends on whether your instance root device is an Amazon EBS volume, or an instance store volume. If you do not know what your instance root device type is, you can find out using the Amazon EC2 console or the command line.

Determining Your Instance Root Device Type

To determine your instance root device type using the console

1. In the navigation pane, click **Events**. Use the filter lists to identify retiring instances, as demonstrated in the procedure above, Identifying instances scheduled for retirement (p. 323).
2. In the **Resource ID** column, click the instance ID to go to the **Instances** page.
3. Select the instance and locate the **Root device type** field in the **Description** tab. If the value is `ebs`, then your instance is EBS-backed. If the value is `instance-store`, then your instance is instance store-backed.
To determine your instance root device type using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-instances` (AWS CLI)
- `ec2-describe-instances` (Amazon EC2 CLI)
- `Get-EC2Instance` (AWS Tools for Windows PowerShell)

Managing Instances Scheduled for Retirement

You can perform one of the actions listed below in order to preserve the data on your retiring instance. It's important that you take this action before the instance retirement date, to prevent unforeseen downtime and data loss.

**Warning**

If your instance store-backed instance passes its retirement date, it's terminated and you cannot recover the instance or any data that was stored on it. Regardless of the root device of your instance, the data on instance store volumes is lost when the instance is retired, even if they are attached to an EBS-backed instance.

Terminate Your Instance

When you've decided that you no longer need an instance, you can terminate it. As soon as the state of an instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance.

You can't connect to or restart an instance after you've terminated it. However, you can launch additional instances using the same AMI. If you'd rather stop and restart your instance, see Stop and Start Your Instance (p. 319).

If your instance is in the `shutting-down` state for longer than usual, it will eventually be cleaned up (terminated) by automated processes within the Amazon EC2 service. For more information, see Troubleshooting Terminating (Shutting Down) Your Instance (p. 637).

Instance Termination

After you terminate an instance, it remains visible in the console for a short while, and then the entry is deleted.

When an instance terminates, the data on any instance store volumes associated with that instance is deleted.

By default, any Amazon EBS volumes that you attach as you launch the instance are automatically deleted when the instance terminates. However, by default, any volumes that you attach to a running instance persist even after the instance terminates. This behavior is controlled by the volume’s `DeleteOnTermination` attribute, which you can modify. For more information, see Preserving Amazon EBS Volumes on Instance Termination (p. 328).

You can prevent an instance from being terminated accidentally by someone using the AWS Management Console, the CLI, and the API. This feature is available for both Amazon EC2 instance store-backed and Amazon EBS-backed instances. Each instance has a `DisableApiTermination` attribute with the default value of `false` (the instance can be terminated through Amazon EC2). You can modify this instance attribute while the instance is running or stopped (in the case of Amazon EBS-backed instances). For more information, see Enabling Termination Protection for an Instance (p. 326).

You can control whether an instance should stop or terminate when shutdown is initiated from the instance using the operating system command for system shutdown. For more information, see Changing the Instance Initiated Shutdown Behavior (p. 327).

If you run a script on instance termination, your instance might have an abnormal termination, because we have no way to ensure that shutdown scripts run. Amazon EC2 attempts to shut an instance down cleanly and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.

Terminating an Instance

You can terminate an instance using the AWS Management Console or the command line.
To terminate an instance using the console

1. Before you terminate the instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console.
3. In the navigation pane, click **Instances**.
4. Select the instance, click **Actions**, and then click **Terminate**.
5. Click **Yes, Terminate** when prompted for confirmation.

To terminate an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Accessing Amazon EC2](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/AccessingEC2.html) (p. 3).

- **terminate-instances** (AWS CLI)
- **ec2-terminate-instances** (Amazon EC2 CLI)
- **Stop-EC2Instance** (AWS Tools for Windows PowerShell)

### Enabling Termination Protection for an Instance

By default, you can terminate your instance using the Amazon EC2 console, command line interface, or API. If you want to prevent your instance from being accidentally terminated using Amazon EC2, you can enable termination protection for the instance. The **DisableApiTermination** attribute controls whether the instance can be terminated using the console, CLI, or API. By default, termination protection is disabled for your instance. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped (for Amazon EBS-backed instances).

The **DisableApiTermination** attribute does not prevent you from terminating an instance by initiating shutdown from the instance (using the operating system command for system shutdown) when the **InstanceInitiatedShutdownBehavior** attribute is set. For more information, see [Changing the Instance Initiated Shutdown Behavior](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/InstanceInitiatedShutdownBehavior.html) (p. 327).

Instances that are part of an Auto Scaling group are not covered by termination protection. For more information, see [Instance Termination Policy for Your Auto Scaling Group](https://docs.aws.amazon.com/autoscaling/userguide/terminating-instead-of-shutting-down.html) in the Auto Scaling Developer Guide.

You can enable or disable termination protection using the AWS Management Console or the command line.

**To enable termination protection for an instance at launch time**

1. On the dashboard of the Amazon EC2 console, click **Launch Instance** and follow the directions in the wizard.
2. On the **Configure Instance Details** page, select the **Enable termination protection** check box.

**To enable termination protection for a running or stopped instance**

1. Select the instance, click **Actions**, and then click **Change Termination Protection**.
2. Click **Yes, Enable**.
To disable termination protection for a running or stopped instance
1. Select the instance, click Actions, and then click Change Termination Protection.
2. Click Yes, Disable.

To enable or disable termination protection using the command line
You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).
- modify-instance-attribute (AWS CLI)
- ec2-modify-instance-attribute (Amazon EC2 CLI)
- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)

Changing the Instance Initiated Shutdown Behavior

By default, when you initiate a shutdown from an Amazon EBS-backed instance using the shutdown command, the instance stops. You can change this behavior using the InstanceInitiatedShutdownBehavior attribute for the instance so that it terminates instead. You can update this attribute while the instance is running or stopped.

You can update the InstanceInitiatedShutdownBehavior attribute using the AWS Management Console or the command line.

To change the shutdown behavior of an instance using the console
1. Open the Amazon EC2 console.
2. In the navigation pane, click Instances.
3. Select the instance, click Actions, and then click Change Shutdown Behavior. The current behavior is already selected.
4. To change the behavior, select an option from the Shutdown behavior list, and then click Apply.

To change the shutdown behavior of an instance using the command line
You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).
- modify-instance-attribute (AWS CLI)
- ec2-modify-instance-attribute (Amazon EC2 CLI)
- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)
Preserving Amazon EBS Volumes on Instance Termination

By default, we do the following:

- Preserve any volumes that you attach to a running instance even after the instance terminates
- Preserve any volumes that you attach to your instance at launch when you stop and restart an instance
- Delete the volumes that you attach to your instance at launch, including the root device volume, when you terminate the instance

You can change this behavior using the `DeleteOnTermination` attribute for the volume. If the value of this attribute is `true`, we delete the volume after the instance terminates; otherwise, we preserve the volume. If the `DeleteOnTermination` attribute of a volume is `false`, the volume persists in its current state. You can take a snapshot of the volume, and you can attach it to another instance.

If you detach a volume that you attached to your instance at launch, and then reattach it, we preserve it even after the instance terminates. In other words, its `DeleteOnTermination` attribute is set to `false`.

You can see the value for the `DeleteOnTermination` attribute on the volumes attached to an instance by looking at the instance’s block device mapping. For more information, see Viewing the EBS Volumes in an Instance Block Device Mapping (p. 601).

You can update the `DeleteOnTermination` attribute using the AWS Management Console or the command line.

Changing the Root Volume to Persist Using the Console

Using the console, you can change the `DeleteOnTermination` attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

To change the root volume of an instance to persist at launch using the console

1. Open the Amazon EC2 console.
2. From the console dashboard, click Launch Instance.
3. On the Choose an Amazon Machine Image (AMI) page, choose an AMI and click Select.
4. Follow the wizard to complete the Choose an Instance Type and Configure Instance Details pages.
5. On the Add Storage page, deselect the Delete On Termination check box for the root volume.
6. Complete the remaining wizard pages, and then click Launch.

You can verify the setting by viewing details for the root device volume on the instance’s details pane. Next to Block devices, click the entry for the root device volume. By default, Delete on termination is True. If you change the default behavior, Delete on termination is False.

Changing the Root Volume of a Running Instance to Persist Using the Command Line

You can use one of the following commands to change the root device volume of a running instance to persist. The root device is typically `/dev/sda1` (Linux) or `xvda` (Windows). For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `modify-instance-attribute` (AWS CLI)
**Example for AWS CLI**

The following command preserves the root volume by setting its `DeleteOnTermination` attributes to `false`.

```bash
aws ec2 modify-instance-attribute --instance-id i-5203422c --block-device-mappings "[{"DeviceName": "/dev/sda1", "Ebs":{"DeleteOnTermination":false}}]"
```

You can confirm that `deleteOnTermination` is `false` by using the `describe-instances` command and looking for the `BlockDeviceMappings` entry for `/dev/sda1` in the command output.

**Example for Amazon EC2 CLI**

The following command preserves the root volume by setting its `DeleteOnTermination` attribute to `false`.

```bash
ec2-modify-instance-attribute i-5203422c -b /dev/sda1::false
```

If you're using the command line tools on a Windows system, you must put quotation marks around the block device mapping value.

```bash
ec2-modify-instance-attribute i-5203422c -b "xvda::false"
```

**Changing the Root Volume of an Instance to Persist at Launch Using the Command Line**

When you launch an instance, you can use one of the following commands to change the root device volume to persist. The root device is typically `/dev/sda1` (Linux) or `xvda` (Windows). For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `run-instances` (AWS CLI)
- `ec2-run-instances` (Amazon EC2 CLI)
- `New-EC2Instance` (AWS Tools for Windows PowerShell)

**Example for AWS CLI**

The following command preserves the root volume by setting its `DeleteOnTermination` attributes to `false`.

```bash
aws ec2 run-instances --image-id ami-1a2b3c4d --block-device-mappings "[{"DeviceName": "/dev/sda1", "Ebs":{"DeleteOnTermination":false}}]"
other parameters...
```

You can confirm that `deleteOnTermination` is `false` by using the `describe-instances` command and looking for the `BlockDeviceMappings` entry for `/dev/sda1` in the command output.
Example for Amazon EC2 CLI

The following command preserves the root volume by setting its `DeleteOnTermination` attribute to `false`.

```
ec2-run-instances ami-1a2b3c4d -b /dev/sda1=::false other parameters... -v
```

If you're using the command line tools on a Windows system, you must put quotation marks around the block device mapping value.

```
ec2-run-instances ami-1a2b3c4d -b "xvda=::false" other parameters... -v
```
Configuring Your Amazon Linux Instance

After you have successfully launched and logged into your instance, you can make changes to it. There are many different ways you can configure an instance to meet the needs of a specific application, and this section contains some common examples to help get you started.

**Important**
These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

**Topics**
- Common Configuration Scenarios (p. 331)
- Managing Software (p. 332)
- Managing Users (p. 340)
- Set the Time for an Instance (p. 341)
- Changing the Hostname for an Instance (p. 344)
- Using Dynamic DNS with Amazon EC2 (p. 347)
- Launching Instances with User Data (p. 349)

**Common Configuration Scenarios**

The base distribution of Amazon Linux contains many software packages and utilities that are required for basic server operations. However, many more software packages are available in various software repositories, and even more packages are available for you to build from source code. For more information on installing and building software from these locations, see Managing Software (p. 332).

Amazon Linux instances come pre-configured with an `ec2-user` account, but you may want to add other user accounts that do not have super-user privileges. For more information on adding and removing user accounts, see Managing Users (p. 340).

The default time configuration for Amazon Linux instances uses Network Time Protocol to set the system time on an instance. The default time zone is UTC. For more information on setting the time zone for an instance or using your own time server, see Set the Time for an Instance (p. 341).
If you have your own network with a domain name registered to it, you can change the hostname of an instance to identify itself as part of that domain. You can also change the system prompt to show a more meaningful name without changing the hostname settings. For more information, see Changing the Hostname for an Instance (p. 344). You can configure an instance to use a dynamic DNS service provider. For more information, see Using Dynamic DNS with Amazon EC2 (p. 347).

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2, cloud-init directives, and shell scripts. For more information, see Launching Instances with User Data (p. 349).

Managing Software

The base distribution of Amazon Linux contains many software packages and utilities that are required for basic server operations. However, many more software packages are available in various software repositories, and even more packages are available for you to build from source code.

Topics
- Updating Instance Software (p. 332)
- Adding Repositories (p. 336)
- Finding Software Packages (p. 337)
- Installing Software Packages (p. 338)
- Preparing to Compile Software (p. 339)

It is important to keep software up-to-date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. For more information, see Updating Instance Software (p. 332).

By default, Amazon Linux instances launch with two repositories enabled: amzn-main and amzn-updates. While there are many packages available in these repositories that are updated by Amazon Web Services, there may be a package that you wish to install that is contained in another repository. For more information, see Adding Repositories (p. 336). For help finding packages in enabled repositories, see Finding Software Packages (p. 337). For information about installing software on an Amazon Linux instance, see Installing Software Packages (p. 338).

Not all software is available in software packages stored in repositories; some software must be compiled on an instance from its source code. For more information, see Preparing to Compile Software (p. 339).

Amazon Linux instances manage their software using the yum package manager. The yum package manager can install, remove, and update software, as well as manage all of the dependencies for each package. Debian-based Linux distributions, like Ubuntu, use the apt-get command and dpkg package manager, so the yum examples in the following sections do not work for those distributions.

Updating Instance Software

It is important to keep software up-to-date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. When you first launch and connect to an Amazon Linux instance, you may see a message asking you to update software packages for security purposes. This section shows how to update an entire system, or just a single package.

Important
These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.
To update all packages on an Amazon Linux instance

1. (Optional) Start a `screen` session in your shell window. Sometimes you may experience a network interruption that can disconnect the SSH connection to your instance. If this happens during a long software update, it can leave the instance in a recoverable, although confused state. A `screen` session allows you to continue running the update even if your connection is interrupted, and you can reconnect to the session later without problems.

   a. Execute the `screen` command to begin the session.

      ```
      [ec2-user ~]$ screen
      ```

   b. If your session is disconnected, log back into your instance and list the available screens.

      ```
      [ec2-user ~]$ screen -ls
      There is a screen on:
      17793 pts-0.ip-12-34-56-78 (Detached)
      1 Socket in /var/run/screen/S-ec2-user.
      ```

   c. Reconnect to the screen using the `screen -r` command and the process ID from the previous command.

      ```
      [ec2-user ~]$ screen -r 17793
      ```

   d. When you are finished using `screen`, use the `exit` command to close the session.

      ```
      [ec2-user ~]$ exit
      [screen is terminating]
      ```

2. Run the `yum update` command. Optionally, you can add the `--security` flag to apply only security updates.

   ```
   [ec2-user ~]$ sudo yum update

2. Review the package information listed, and type y and Enter to accept the update or updates. Sometimes there will be more than one package listed if there are package dependencies that must be resolved. The `yum` output shows the status of the update while it is running.
Adding Repositories

By default, Amazon Linux instances launch with two repositories enabled: amzn-main and amzn-updates. While there are many packages available in these repositories that are updated by Amazon Web Services, there may be a package that you wish to install that is contained in another repository.

**Important**

These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

To install a package from a different repository with **yum**, you need to add the repository information to the `/etc/yum.conf` file or to its own `repository.repo` file in the `/etc/yum.repos.d` directory. You can do this manually, but most yum repositories provide their own `repository.repo` file at their repository URL.

**To add a yum repository to `/etc/yum.repos.d`**

1. Find the location of the `.repo` file. This will vary depending on the repository you are adding. In this example, the `.repo` file is at `https://www.example.com/repository.repo`.
2. Add the repository with the `yum-config-manager` command.

```
[ec2-user ~]$ sudo yum-config-manager --add-repo https://www.example.com/repository.repo
Loaded plugins: priorities, update-motd, upgrade-helper
adding repo from: https://www.example.com/repository.repo
grabbing file https://www.example.com/repository.repo to /etc/yum.repos.d/repository.repo
repository.repo                                      | 4.0 kB     00:00
repo saved to /etc/yum.repos.d/repository.repo
```

```
To enable a yum repository in `/etc/yum.repos.d`

- Use the `yum-config-manager` command with the `--enable repository` flag. The following command enables the Extra Packages for Enterprise Linux (EPEL) repository from the Fedora project. By default, this repository is present in `/etc/yum.repos.d` on Amazon Linux instances, but it is not enabled.

```bash
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

## Finding Software Packages

You can use the `yum search` command to search the descriptions of packages that are available in your configured repositories. This is especially helpful if you don't know the exact name of the package you want to install. Simply append the keyword search to the command; for multiple word searches, wrap the search query with quotation marks.

**Important**

These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

Multiple word search queries in quotation marks only return results that match the exact query. If you don't see the expected package, simplify your search to one keyword and then scan the results. You can also try keyword synonyms to broaden your search.

```bash
[ec2-user ~]$ sudo yum search "find"
```

```
Loaded plugins: priorities, security, update-motd, upgrade-helper
================================ N/S Matched: find ===============================
findutils.x86_64 : The GNU versions of find utilities (find and xargs)
perl-File-Find-Rule.noarch : Perl module implementing an alternative interface to File::Find
perl-Module-Find.noarch : Find and use installed modules in a (sub)category
libpuzzle.i686 : Library to quickly find visually similar images (gif, png, jpg)
libpuzzle.x86_64 : Library to quickly find visually similar images (gif, png, jpg)
mlocate.x86_64 : An utility for finding files by name
```

The yum package manager also combines several packages into groups that you can install with one command to perform a particular task, such as installing a web server or build tools for software compilation. To list the groups that are already installed on your system and the available groups that you can install, use the `yum grouplist` command.

```bash
[ec2-user ~]$ sudo yum grouplist
```

```
Loaded plugins: priorities, security, update-motd, upgrade-helper
Setting up Group Process
Installed Groups:
  Development Libraries
  Development tools
  Editors
  Legacy UNIX compatibility
  Mail Server
  MySQL Database
```

API Version 2014-02-01
You can see the different packages in a group by using the `yum groupinfo "Group Name"` command, replacing `Group Name` with the name of the group to get information about. This command lists all of the mandatory, default, and optional packages that can be installed with that group.

## Installing Software Packages

The yum package manager is a great tool for installing software, because it can search all of your enabled repositories for different software packages and also handle any dependencies in the software installation process.

### Important

These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

To install a package from a repository, use the `yum install package` command, replacing `package` with the name of the software to install. For example, to install the `links` text-based web browser, enter the following command.

```
[ec2-user ~]$ sudo yum install links
```

To install a group of packages, use the `yum groupinstall Group Name` command, replacing `Group Name` with the name of the group you would like to install. For example, to install the "Performance Tools" group, enter the following command.

```
[ec2-user@ip-10-161-113-54 ~]$ sudo yum groupinstall "Performance Tools"
```

By default, yum will only install the mandatory and default packages in the group listing. If you would like to install the optional packages in the group also, you can set the `group_package_types` configuration parameter in the command when you execute it that adds the optional packages.

```
[ec2-user ~]$ sudo yum --setopt=group_package_types=mandatory,default,optional groupinstall "Performance Tools"
```
You can also use `yum install` to install RPM package files that you have downloaded from the Internet. To do this, simply append the path name of an RPM file to the installation command instead of a repository package name.

```
[ec2-user ~]$ sudo yum install my-package.rpm
```

## Preparing to Compile Software

There is a wealth of open-source software available on the Internet that has not been pre-compiled and made available for download from a package repository. You may eventually discover a software package that you need to compile yourself, from its source code. For your system to be able to compile software, you need to install several development tools, such as `make`, `gcc`, and `autoconf`.

**Important**

These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

Because software compilation is not a task that every Amazon EC2 instance requires, these tools are not installed by default, but they are available in a package group called "Development Tools" that is easily added to an instance with the `yum groupinstall` command.

```
[ec2-user ~]$ sudo yum groupinstall "Development Tools"
```

Software source code packages are often available for download (from web sites such as https://github.com/ and http://sourceforge.net/) as a compressed archive file, called a tarball. These tarballs will usually have the `.tar.gz` file extension. You can decompress these archives with the `tar` command.

```
[ec2-user ~]$ tar -xzf software.tar.gz
```

After you have decompressed and unarchived the source code package, you should look for a `README` or `INSTALL` file in the source code directory that can provide you with further instructions for compiling and installing the source code.

### To retrieve source code for Amazon Linux packages

Amazon Web Services provides the source code for maintained packages. You can download the source code for any installed packages with the `get_reference_source` command.

- Run the `get_reference_source -p package` command to download the source code for `package`. For example, to download the source code for the `htop` package, enter the following command.

```
[ec2-user ~]$ get_reference_source -p htop
```

Requested package: htop

Found package from local RPM database: htop-1.0.1-2.3.amzn1.x86_64

Corresponding source RPM to found package: htop-1.0.1-2.3.amzn1.src.rpm

Are these parameters correct? Please type 'yes' to continue: yes

Source RPM downloaded to: /usr/src/srpm/debug/htop-1.0.1-2.3.amzn1.src.rpm

The command output lists the location of the source RPM, in this case

/usr/src/srpm/debug/htop-1.0.1-2.3.amzn1.src.rpm.
Managing Users

Each Linux instance type launches with a default user account. For Amazon Linux, the default user name is `ec2-user`. For RHEL5, the user name is often `root` but might be `ec2-user`. For Ubuntu, the user name is `ubuntu`. For SUSE Linux, the user name is `root`. Otherwise, check with your AMI provider.

Using the default user account is adequate for many applications, but you may choose to add user accounts so that individuals can have their own files and workspaces. Creating user accounts for new users is much more secure than granting multiple (possibly inexperienced) users access to the `ec2-user` account, since that account can cause a lot of damage to a system when used improperly.

To add a new user to the system

Effectively adding users to an Amazon Linux instance involves two basic operations: adding the user to the system, and providing that user with a way to log in remotely.

1. To add a new user to the system, use the `useradd` command followed by the name of the user you wish to create.

   ```
   [ec2-user ~]$ sudo useradd newuser
   ```

   This command adds the `newuser` account to the system (with an entry in the `/etc/passwd` file), creates a `newuser` group, and creates a home directory for the account in `/home/newuser`.

2. To provide remote access to this account, you must create a `.ssh` directory in the `newuser` home directory and create a file within it named "authorized_keys" that contains a public key.

   a. Switch to the new account so that newly created files have the proper ownership.

      ```
      [ec2-user ~]$ sudo su - newuser
      [newuser ~]$
      ```

      Note that the prompt now says `newuser` instead of `ec2-user`; you have switched the shell session to the new account.

   b. Create a `.ssh` directory for the `authorized_keys` file.

      ```
      [newuser ~]$ mkdir .ssh
      ```

   c. Change the file permissions of the `.ssh` directory to 700 (this means only the file owner can read, write, or open the directory).

      **Important**
      This step is very important; without these exact file permissions, you will not be able to log into this account using SSH.

      ```
      [newuser ~]$ chmod 700 .ssh
      ```

   d. Create a file named "authorized_keys" in the `.ssh` directory.

      ```
      [newuser ~]$ touch .ssh/authorized_keys
      ```

   e. Change the file permissions of the `authorized_keys` file to 600 (this means only the file owner can read or write to the file).
**Important**
This step is very important; without these exact file permissions, you will not be able to log into this account using SSH.

[newuser ~]$ chmod 600 .ssh/authorized_keys

f. Edit the `authorized_keys` file with your favorite text editor and paste the public key for your key pair into the file.

**Note**
For more information about creating a key pair or retrieving a public key from an existing key pair, see Amazon EC2 Key Pairs (p. 433)

You should now be able to log into the `newuser` account on your instance via SSH using the private key that matches the public key from Step 2.f (p. 341).

**To remove a user from the system**

If a user account is no longer needed, you can remove that account so that it may no longer be used.

- To delete a user account, the user’s home directory, and the user’s mail spool, execute the `userdel` `-r` command followed by the user name you wish to delete.

[ec2-user ~]$ sudo userdel -r olduser

**Note**
To keep the user’s home directory and mail spool, omit the `-r` option.

**Set the Time for an Instance**

A consistent and accurate time reference is crucial for many server tasks and processes. Most system logs include a time stamp that you can use to determine when problems occur and in what order the events take place. Network Time Protocol (NTP) is configured by default on Amazon Linux instances, and the system time is synchronized with a load-balanced pool of public servers on the Internet and set to the UTC time zone. For more information about NTP, go to [http://www.ntp.org/](http://www.ntp.org/).

**Topics**

- Changing the Time Zone (p. 342)
- Configuring Network Time Protocol (NTP) (p. 342)

The procedures in this section show how to set the time zone on an instance as well as configure and verify NTP operation.

**Important**
These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.
Changing the Time Zone

Amazon Linux instances are set to the UTC (Coordinated Universal Time) time zone by default, but you may wish to change the time on an instance to the local time or to another time zone in your network.

To change the time zone on an instance

1. Identify the time zone to use on the instance. The /usr/share/zoneinfo directory contains a hierarchy of time zone data files. Browse the directory structure at that location to find a file for your time zone.

   [ec2-user ~]$ ls /usr/share/zoneinfo
   Africa      Chile    GB         Indian       Mideast   posixrules US
   America     CST6CDT  GB-Eire    Iran         MST       PRC         UTC
   Antarctica  Cuba     GMT        iso3166.tab  MST7MDT   PST8PDT     WET
   Arctic      EET      GMT0       Israel       Navajo    right       W-SU
   ...

   Some of the entries at this location are directories (such as America), and these directories contain time zone files for specific cities. Find your city (or a city in your time zone) to use for the instance. In this example, you can use the time zone file for Los Angeles, /usr/share/zoneinfo/America/Los_Angeles.

2. Update the /etc/sysconfig/clock file with the new time zone.

   a. Open the /etc/sysconfig/clock file with your favorite text editor (such as vim or nano). You need to use sudo with your editor command because /etc/sysconfig/clock is owned by root.

   b. Locate the ZONE entry, and change it to the time zone file (omitting the /usr/share/zoneinfo section of the path). For example, to change to the Los Angeles time zone, change the ZONE entry to the following.

      ZONE="America/Los_Angeles"

   c. Save the file and exit the text editor.

3. Create a symbolic link between /etc/localtime and your time zone file so that the instance finds the time zone file when it references local time information.

   [ec2-user ~]$ sudo ln -sf /usr/share/zoneinfo/America/Los_Angeles /etc/localtime

4. Reboot the system to pick up the new time zone information in all services and applications.

   [ec2-user ~]$ sudo reboot

Configuring Network Time Protocol (NTP)

Network Time Protocol (NTP) is configured by default on Amazon Linux instances; however, an instance needs access to the Internet for the standard NTP configuration to work. The procedures in this section show how to verify that the default NTP configuration is working correctly. If your instance does not have
access to the Internet, you need to configure NTP to query a different server in your private network to keep accurate time.

To verify that NTP is working properly

1. Use the `ntpstat` command to view the status of the NTP service on the instance.

   ```
   [ec2-user ~]$ ntpstat
   ```

   If your output resembles the output below, then NTP is working properly on the instance.

   ```
   synchronised to NTP server (12.34.56.78) at stratum 3
   time correct to within 399 ms
   polling server every 64 s
   ```

   If your output states, "unsynchronised", wait a minute and try again. The first synchronization may take a minute to complete.

   If your output states, "Unable to talk to NTP daemon. Is it running?", you probably need to start the NTP service and enable it to automatically start at boot time.

2. (Optional) You can use the `ntpq -p` command to see a list of peers known to the NTP server and a summary of their state.

   ```
   [ec2-user ~]$ ntpq -p
   remote           refid      st  t when poll reach   delay   offset  jitter
   ===============================================================================
   +lttleman.deekay 204.9.54.119     2 u   15  128  377   88.649    5.946  6.876
   -bittorrent.tomh 91.189.94.4      3 u  133  128  377  182.673    8.001 1.278
   +tesla.selinc.co 149.20.64.28     2 u   31  128  377   28.586   -1.215 1.435
   ```

To start and enable NTP

1. Start the NTP service with the following command.

   ```
   [ec2-user ~]$ sudo service ntpd start
   Starting ntpd: [ OK ]
   ```

2. Enable NTP to start at boot time with the `chkconfig` command.

   ```
   [ec2-user ~]$ sudo chkconfig ntpd on
   ```

3. Verify that NTP is enabled with the following command.

   ```
   [ec2-user ~]$ sudo chkconfig --list ntpd
   ntpd          0:off 1:off 2:on 3:on 4:on 5:on 6:off
   ```
Here `ntpd` is on in runlevels 2, 3, 4, and 5, which is correct.

**To change NTP servers**

You may decide not to use the standard NTP servers or you may need to use your own NTP server within your private network for instances that do not have Internet access.

1. Open the `/etc/ntp.conf` file in your favorite text editor (such as `vim` or `nano`). You need to use `sudo` with the editor command because `/etc/ntp.conf` is owned by `root`.
2. Find the `server` section, which defines the servers to poll for NTP configuration.

```plaintext
# Use public servers from the pool.ntp.org project.
# Please consider joining the pool (http://www.pool.ntp.org/join.html).
server 0.amazon.pool.ntp.org iburst
server 1.amazon.pool.ntp.org iburst
server 2.amazon.pool.ntp.org iburst
server 3.amazon.pool.ntp.org iburst
```

3. Comment out the servers you don't want to use by adding a "#" character to the beginning of those server definitions.

```plaintext
# Use public servers from the pool.ntp.org project.
# Please consider joining the pool (http://www.pool.ntp.org/join.html).
#server 0.amazon.pool.ntp.org iburst
#server 1.amazon.pool.ntp.org iburst
#server 2.amazon.pool.ntp.org iburst
#server 3.amazon.pool.ntp.org iburst
```

4. Add an entry for each server to poll for time synchronization. You can use a DNS name for this entry or a dotted quad IP address (such as `10.0.0.254`).

```plaintext
server my-ntp-server.my-domain.com iburst
```

5. Restart the NTP service to pick up the new servers.

```
[ec2-user ~]$ sudo service ntpd start
Starting ntpd:                                               [  OK  ]
```

6. Verify that your new settings work and that NTP is functioning.

```
[ec2-user ~]$ ntpstat
synchronised to NTP server (64.246.132.14) at stratum 2
time correct to within 99 ms
```

**Changing the Hostname for an Instance**

When you launch an instance, it is assigned a hostname that is a form of the private, internal IP address. A typical Amazon EC2 private DNS name looks something like this:

`ip-12-34-56-78.us-west-2.compute.internal`, where the name consists of the internal domain,
the service (in this case, compute), the region, and a form of the private IP address. Part of this hostname is displayed at the shell prompt when you log into your instance (for example, ip-12-34-56-78). Each time you stop and restart your Amazon EC2 instance (unless you are using an Elastic IP address), the public and private IP addresses change, and so does your public DNS name, system hostname, and shell prompt.

**Important**
These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

### Changing the System Hostname

If you have a public DNS name registered for the IP address of your instance (such as webserver.mydomain.com), you can set the system hostname so your instance identifies itself as a part of that domain. This also changes the shell prompt so that it displays the first portion of this name instead of the hostname supplied by AWS (for example, ip-12-34-56-78). If you do not have a public DNS name registered, you can still change the hostname, but the process is a little different.

#### To change the system hostname to a public DNS name

Follow this procedure if you already have a public DNS name registered.

1. Open the /etc/sysconfig/network configuration file in your favorite text editor and change the `HOSTNAME` entry to reflect the fully qualified domain name (such as webserver.mydomain.com).

   ```
   HOSTNAME=webserver.mydomain.com
   ```

2. Reboot the instance to pick up the new hostname.

   ```
   [ec2-user ~] $ sudo reboot
   ```

3. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the `hostname` command should show the fully qualified domain name.

   ```
   [ec2-user@webserver ~] $ hostname
   webserver.mydomain.com
   ```

#### To change the system hostname without a public DNS name

1. Open the /etc/sysconfig/network configuration file in your favorite text editor and change the `HOSTNAME` entry to reflect the desired system hostname (such as webserver).

   ```
   HOSTNAME=webserver.localdomain
   ```

2. Open the /etc/hosts file in your favorite text editor and change the entry beginning with 127.0.0.1 to match the example below, substituting your own hostname.

   ```
   127.0.0.1 webserver.localdomain webserver localhost localhost.localdomain
   ```
3. Reboot the instance to pick up the new hostname.

```
[ec2-user ~]$ sudo reboot
```

4. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the `hostname` command should show the fully qualified domain name.

```
[ec2-user@webserver ~]$ hostname
webserver.localdomain
```

## Changing the Shell Prompt Without Affecting the Hostname

If you do not want to modify the hostname for your instance, but you would like to have a more useful system name (such as `webserver`) displayed than the private name supplied by AWS (for example, `ip-12-34-56-78`), you can edit the shell prompt configuration files to display your system nickname instead of the hostname.

### To change the shell prompt to a host nickname

1. Create a file in `/etc/profile.d` that sets the environment variable called `NICKNAME` to the value you want in the shell prompt. For example, to set the system nickname to `webserver`, execute the following command.

```
[ec2-user ~]$ sudo sh -c 'echo "export NICKNAME=webserver" > /etc/profile.d/prompt.sh'
```

2. Open the `/etc/bashrc` file in your favorite text editor (such as `vim` or `nano`). You need to use `sudo` with the editor command because `/etc/bashrc` is owned by `root`.

3. Edit the file and change the shell prompt variable (`PS1`) to display your nickname instead of the hostname. Find the following line that sets the shell prompt in `/etc/bashrc` (several surrounding lines are shown below for context; look for the line that starts with `"$PS1"`):

   ```
   # Turn on checkwinsize
   shopt -s checkwinsize
   [ "$PS1" = "\s-\v\$ " ] && PS1="[\u8\h \W]\$ \\
   # You might want to have e.g. tty in prompt (e.g. more virtual machines)
   # and console windows
   
   And change the `\h` (the symbol for `hostname`) in that line to the value of the `NICKNAME` variable.
   ```

4. (Optional) To set the title on shell windows to the new nickname, complete the following steps.
a. Create a file called /etc/sysconfig/bash-prompt-xterm.

```
[ec2-user ~]$ sudo touch /etc/sysconfig/bash-prompt-xterm
```

b. Make the file executable with the following command.

```
[ec2-user ~]$ sudo chmod +x /etc/sysconfig/bash-prompt-xterm
```

c. Open the /etc/sysconfig/bash-prompt-xterm file in your favorite text editor (such as vim or nano). You need to use sudo with the editor command because /etc/sysconfig/bash-prompt-xterm is owned by root.

d. Add the following line to the file.

```
echo -ne "\033[0;${USER}@${NICKNAME}:${PWD/#$HOME/~}\007"
```

5. Log out and then log back in to pick up the new nickname value.

### Using Dynamic DNS with Amazon EC2

When you launch an Amazon EC2 instance, it is assigned a public IP address and a public DNS (Domain Name System) name that you can use to reach it from the Internet. Because there are so many hosts in the Amazon Web Services domain, these public names must be quite long for each name to remain unique. A typical Amazon EC2 public DNS name looks something like this: ec2-12-34-56-78.us-west-2.compute.amazonaws.com, where the name consists of the Amazon Web Services domain, the service (in this case, compute), the region, and a form of the public IP address.

Dynamic DNS services provide custom DNS host names within their domain area that can be easy to remember and that can also be more relevant to your host's use case; some of these services are also free of charge. You can use a dynamic DNS provider with Amazon EC2 and configure the instance to update the IP address associated with a public DNS name each time the instance starts. There are many different providers to choose from, and the specific details of choosing a provider and registering a name with them are outside the scope of this guide. A simple web search of “dynamic DNS” should return multiple results for service providers, many of whom provide this service for free.

**Important**

These procedures are intended for use with Amazon Linux, but the commands and file locations are similar for Red Hat and CentOS. For more information about other distributions, see their specific documentation.

### To use dynamic DNS with Amazon EC2

1. Sign up with a dynamic DNS service provider and register a public DNS name with their service. In this procedure, you can use the free service from no-ip.com/free.

2. Configure the dynamic DNS update client. After you have a dynamic DNS service provider and a public DNS name registered with their service, point the DNS name to the IP address for your instance. Many providers allow you to do this manually from your account page on their website, but many also allow you to do this automatically with a software update client. In this example, you can use the noip2 client, which only works with the service provided by no-ip.com.
Note
Other service providers may offer their own client, or you may be able to configure the ddclient update utility to work with their service. For more information, see the specific documentation for your service provider and http://sourceforge.net/p/ddclient/wiki/Home/.

a. Enable the Extra Packages for Enterprise Linux (EPEL) repository to gain access to the noip client. The ddclient package is also available in this repository, but the configuration steps that follow are different.

```bash
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

b. Install the noip package.

```bash
[ec2-user ~]$ sudo yum install -y noip
```

c. Create the noip2 configuration file. Enter the login and password information for when prompted and answer the subsequent questions to configure the client.

```bash
[ec2-user ~]$ sudo noip2 -C
```

3. Enable the noip service with the chkconfig command.

```bash
[ec2-user ~]$ sudo chkconfig noip on
```

You can verify that the service is enabled with the chkconfig --list command.

```bash
[ec2-user ~]$ chkconfig --list noip
noip    0:off 1:off 2:on 3:on 4:on 5:on 6:off
```

Here, noip is on in runlevels 2, 3, 4, and 5 (which is correct). Now the update client starts at every boot and updates the public DNS record to point to the IP address of the instance.

4. Start the noip service.

```bash
[ec2-user ~]$ sudo service noip start
Starting noip2:                                  [ OK ]
```

This command starts the client, which reads the configuration file (/etc/no-ip2.conf) that you created earlier and updates the IP address for the public DNS name that you chose.

5. Verify that the update client has set the correct IP address for your dynamic DNS name. Allow a few minutes for the DNS records to update, and then try to connect to your instance via SSH with the public DNS name that you configured in this procedure.
Launching Instances with User Data

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common automated configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: shell scripts and cloud-init directives. You can also pass this data into the launch wizard as plain text, as a file (this is useful for launching instances via the command line tools), or as base64-encoded text (for API calls).

If you are interested in more complex automation scenarios, consider using AWS CloudFormation and AWS OpsWorks. For more information, see the AWS CloudFormation User Guide and the AWS OpsWorks User Guide.

Topics

- User Data and Shell Scripts (p. 349)
- User Data and cloud-init Directives (p. 351)

In the following examples, the commands from the Installing a LAMP Web Server tutorial (p. 34) are converted to a shell script and a set of cloud-init directives that executes when the instance launches. In each example, the following tasks are executed by the user data:

- The distribution software packages are updated.
- The necessary web server, php, and mysql packages are installed.
- The httpd service is started and turned on via chkconfig.
- The www group is added, and the ec2-user is added to that group.
- The appropriate ownership and file permissions are set for the web directory and the files contained within it.
- A simple web page is created to test the web server and php engine.

Prerequisites

The following examples assume that your instance has a public DNS name that is reachable from the Internet. For more information, see Launch an Amazon EC2 Instance (p. 25). You must also configure your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see Setting Up with Amazon EC2 (p. 19).

Also, these instructions are intended for use with Amazon Linux, and the commands and directives may not work for other Linux distributions. For more information about other distributions, such as their support for cloud-init, see their specific documentation.

User Data and Shell Scripts

If you are familiar with shell scripting, this is the easiest and most complete way to send instructions to an instance at launch, and the cloud-init log file (/var/log/cloud-init.log) captures console output so it is easy to debug your scripts following a launch if the instance does not behave the way you intended.

Important

User data scripts and cloud-init directives only run during the first boot cycle when an instance is launched.

User data shell scripts must start with the #! characters and the path to the interpreter you want to read the script (commonly /bin/bash). For a great introduction on shell scripting, see the BASH Programming HOW-TO at the Linux Documentation Project (tldp.org).
Scripts entered as user data are executed as the root user, so do not use the sudo command in the script. Remember that any files you create will be owned by root; if you need non-root users to have file access, you should modify the permissions accordingly in the script. Also, because the script is not run interactively, you cannot include commands that require user feedback (such as yum update without the -y flag).

Adding these tasks at boot time adds to the amount of time it takes to boot the instance. You should allow a few minutes of extra time for the tasks to complete before you test that the user script has finished successfully.

To pass a shell script to an instance with user data

1. Follow the procedure for launching an instance at Launching Your Instance from an AMI (p. 301), but when you get to Step 6 (p. 302), paste the user data script text into the User data field and then complete the launch procedure. For the example below, the script creates and configures our web server.

```
#!/bin/bash
yum update -y
yum groupinstall -y "Web Server" "MySQL Database" "PHP Support"
yum install -y php-mysql
service httpd start
chkconfig httpd on
groupadd www
usermod -a -G www ec2-user
chown -R root:www /var/www
chmod 2775 /var/www
find /var/www -type d -exec chmod 2775 {} +
find /var/www -type f -exec chmod 0664 {} +
```

2. Allow enough time for the instance to launch and execute the commands in your script, and then check to see that your script has completed the tasks that you intended. For our example, in a web browser, enter the URL of the PHP test file the script created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page.

**Tip**

If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For information about adding an HTTP rule to your security group, see Adding Rules to a Security Group (p. 445).

3. (Optional) If your script did not accomplish the tasks you were expecting it to, or if you just want to verify that your script completed without errors, examine the cloud-init log file at /var/log/cloud-init.log and look for error messages in the output.

For additional debugging information, you can create a Mime multipart archive that includes a cloud-init data section with the following directive:

```
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends command output from your script to /var/log/cloud-init-output.log. For more information on cloud-init data formats and creating Mime multipart archive, see cloud-init Formats.
User Data and `cloud-init` Directives

The `cloud-init` package configures specific aspects of a new Amazon Linux instance when it is launched; most notably, it configures the `.ssh/authorized_keys` file for the `ec2-user` so you can log in with your own private key.

The `cloud-init` user directives can be passed to an instance at launch the same way that a script is passed, although the syntax is different. For more information about `cloud-init`, go to http://cloudinit.readthedocs.org/en/latest/index.html.

**Important**

User data scripts and `cloud-init` directives only run during the first boot cycle when an instance is launched.

The Amazon Linux version of `cloud-init` does not support all of the directives that are available in the base package, and some of the directives have been renamed (such as `repo_update` instead of `apt-upgrade`). For a more complete set of `cloud-init` examples that work with Amazon Linux, see the example file on a running Amazon Linux instance at /usr/share/doc/cloud-init-0.5.15/examples/cloud-init-amzn.txt.

Adding these tasks at boot time adds to the amount of time it takes to boot an instance. You should allow a few minutes of extra time for the tasks to complete before you test that your user data directives have completed.

**To pass `cloud-init` directives to an instance with user data**

1. Follow the procedure for launching an instance at Launching Your Instance from an AMI (p. 301), but when you get to Step 6 (p. 302), paste your `cloud-init` directive text into the User data field and then complete the launch procedure. For the example below, the directives create and configure a web server.

```
#cloud-config
repo_update: true
repo_upgrade: all

packages:
- httpd
- crypto-utils
- mod_perl
- mod_ssl
- mod_wsgi
- mysql-server
- php
- php-gd
- php-pdo
- php-pear
- php-xml
- php-mysql

runcmd:
- service httpd start
- chkconfig httpd on
- groupadd www
  - [ sh, -c, "usermod -a -G www ec2-user" ]
  - [ sh, -c, "chown -R root:www /var/www" ]
- chmod 2775 /var/www
  - [ find, /var/www, -type, d, -exec, chmod, 2775, {}, + ]
```
2. Allow enough time for the instance to launch and execute the directives in your user data, and then check to see that your directives have completed the tasks you intended. For our example, in a web browser, enter the URL of the PHP test file the directives created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

http://my.public.dns.amazonaws.com/phpinfo.php

You should see the PHP information page.

**Tip**

If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For information about adding an HTTP rule to your security group, see Adding Rules to a Security Group (p. 445).

3. (Optional) If your directives did not accomplish the tasks you were expecting them to, or if you just want to verify that your directives completed without errors, examine the cloud-init log file at /var/log/cloud-init.log and look for error messages in the output. For additional debugging information, you can add the following line to your directives:

```plaintext
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends runcmd output to /var/log/cloud-init-output.log.
Monitoring Amazon EC2

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon Elastic Compute Cloud (Amazon EC2) instances and your AWS solutions. You should collect monitoring data from all of the parts in your AWS solutions so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon EC2, however, you should create a monitoring plan that should include:

- What are your goals for monitoring?
- What resources you will monitor?
- How often you will monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

After you have defined your monitoring goals and have created your monitoring plan, the next step is to establish a baseline for normal Amazon EC2 performance in your environment. You should measure Amazon EC2 performance at various times and under different load conditions. As you monitor Amazon EC2, you should store a history of monitoring data that you’ve collected. You can compare current Amazon EC2 performance to this historical data to help you to identify normal performance patterns and performance anomalies, and devise methods to address them. For example, you can monitor CPU utilization, disk I/O, and network utilization for your Amazon EC2 instances. When performance falls outside your established baseline, you might need to reconfigure or optimize the instance to reduce CPU utilization, improve disk I/O, or reduce network traffic.

To establish a baseline you should, at a minimum, monitor the following items:

<table>
<thead>
<tr>
<th>Item to Monitor</th>
<th>Amazon EC2 Metric</th>
<th>Monitoring Script</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU utilization</td>
<td>CPUUtilization</td>
<td></td>
</tr>
<tr>
<td>Memory utilization</td>

<td>Monitoring Scripts for Amazon EC2 Instances</td>
</tr>
<tr>
<td>Memory used</td>

<td>Monitoring Scripts for Amazon EC2 Instances</td>
</tr>
<tr>
<td>Memory available</td>
<td></td>
<td>Monitoring Scripts for Amazon EC2 Instances</td>
</tr>
</tbody>
</table>
### Automated and Manual Monitoring

AWS provides various tools that you can use to monitor Amazon EC2. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention.

**Topics**
- Automated Monitoring Tools (p. 354)
- Manual Monitoring Tools (p. 355)

#### Automated Monitoring Tools

You can use the following automated monitoring tools to watch Amazon EC2 and report back to you when something is wrong:

- **System Status Checks** - monitor the AWS systems required to use your instance to ensure they are working properly. These checks detect problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue or you can resolve it yourself (for example, by stopping and restarting or terminating and replacing an instance). Examples of problems that cause system status checks to fail include:
  - Loss of network connectivity
  - Loss of system power
  - Software issues on the physical host

### Monitoring Scripts for Amazon EC2 Instances

Manual Monitoring Tools

Another important part of monitoring Amazon EC2 involves manually monitoring those items that the monitoring scripts, status checks, and CloudWatch alarms don't cover. The Amazon EC2 and CloudWatch console dashboards provide an at-a-glance view of the state of your Amazon EC2 environment.

- **Amazon EC2 Dashboard** shows:
  - Service Health and Scheduled Events by region
  - Instance state
  - Status checks
  - Alarm status
  - Instance metric details (In the navigation pane click **Instances**, select an instance, and then click the **Monitoring** tab)
  - Volume metric details (In the navigation pane click **Volumes**, select a volume, and then click the **Monitoring** tab)

- **Amazon CloudWatch Dashboard** shows:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status
In addition, you can use CloudWatch to do the following:

- Graph Amazon EC2 monitoring data to troubleshoot issues and discover trends
- Search and browse all your AWS resource metrics
- Create and edit alarms to be notified of problems
- See at-a-glance overviews of your alarms and AWS resources

### Best Practices for Monitoring

Use the following best practices for monitoring to help you with your Amazon EC2 monitoring tasks.

- Make monitoring a priority to head off small problems before they become big ones.
- Create and implement a monitoring plan that collects monitoring data from all of the parts in your AWS solution so that you can more easily debug a multi-point failure if one occurs. Your monitoring plan should address, at a minimum, the following questions:
  - What are your goals for monitoring?
  - What resources you will monitor?
  - How often you will monitor these resources?
  - What monitoring tools will you use?
  - Who will perform the monitoring tasks?
  - Who should be notified when something goes wrong?
- Automate monitoring tasks as much as possible.
- Check the log files on your EC2 instances.

### Monitoring the Status of Your Instances

You can monitor the status of your instances by viewing status checks and scheduled events for your instances. A status check gives you the information that results from automated checks performed by Amazon EC2. These automated checks detect whether specific issues are affecting your instances. The status check information, together with the data provided by Amazon CloudWatch, gives you detailed operational visibility into each of your instances.

You can also see status on specific events scheduled for your instances. Events provide information about upcoming activities such as rebooting or retirement that are planned for your instances, along with the scheduled start and end time of each event.

### Monitoring Instances with Status Checks

With instance status monitoring you can quickly determine whether Amazon EC2 has detected any problems that may prevent your instances from running applications. Amazon EC2 performs automated checks on every running Amazon EC2 instance to identify hardware and software issues. You can view the results of these status checks to identify specific and detectable problems. This data augments the information that Amazon EC2 already provides about the intended state of each instance (pending, running, stopping, etc.) as well as the utilization metrics that Amazon CloudWatch monitors (CPU utilization, network traffic, and disk activity).
Status checks are performed every five minutes and each returns a pass or a fail status. If all checks pass, the overall status of the instance is **OK**. If one or more checks fail, the overall status is **impaired**.

Status checks are built into Amazon EC2, so they cannot be disabled or deleted. You can, however, create or delete alarms that are triggered based on the result of the status checks. For example, you can create an alarm to warn you if status checks fail on a specific instance. For more information, see [Creating and Editing Status Check Alarms](p. 359).

There are two types of status checks: system status checks and instance status checks.

**System status checks** monitor the AWS systems required to use your instance to ensure they are working properly. These checks detect problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue or you can resolve it yourself (for example, by stopping and restarting or terminating and replacing an instance). Examples of problems that cause system status checks to fail include:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host

**Instance status checks** monitor the software and network configuration of your individual instance. These checks detect problems that require your involvement to repair. When an instance status check fails, typically you will need to address the problem yourself (for example, by rebooting the instance or by making modifications in your operating system). Examples of problems that may cause instance status checks to fail include:

- Failed system status checks
- Misconfigured networking or startup configuration
- Exhausted memory
- Corrupted file system
- Incompatible kernel

**Note**

Status checks that occur during instance reboot or while a Windows instance store-backed instance is being bundled will report an instance status check failure until the instance becomes available again.

**Viewing Status**

AWS provides you with several ways to view and work with status checks: You can use the AWS Management Console, interact directly with the API, or use the command line interface.

**Amazon EC2 Console**

To view status checks using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, click **Instances**.
3. On the **Instances** page, the **Status Checks** column lists the operational status of each instance.
4. To view an individual instance’s status, select the instance, and then click the **Status Checks** tab.
**Note**
If you have an instance with a failed status check and the instance has been unreachable for over 20 minutes, you can click **Contact AWS Support** to submit a request for assistance. To try and troubleshoot system or instance status check failures yourself, see Troubleshooting Instances with Failed Status Checks (p. 638).

### Command Line Interface

<table>
<thead>
<tr>
<th>To do this</th>
<th>Run this command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get the status of all instances</td>
<td><code>describe-instance-status</code></td>
</tr>
<tr>
<td>Get the status of all instances with a instance status of impaired</td>
<td><code>describe-instance-status --filters Name=instance-status.status,Values=impaired</code></td>
</tr>
<tr>
<td>Get the status of a single instance with instance ID i-15a4417c</td>
<td><code>describe-instance-status --instance-ids -i-i-15a4417c</code></td>
</tr>
</tbody>
</table>

For more information about using the `describe-instance-status` command, see `describe-instance-status` in the *AWS Command Line Interface Reference*.

**Note**
If you have an instance with a failed status check, see Troubleshooting Instances with Failed Status Checks (p. 638)

### API

You can use the `DescribeInstanceStatus` action to retrieve the status of your instances. For more information, see `DescribeInstanceStatus` in the *Amazon Elastic Compute Cloud API Reference*.

### Reporting Status

You can provide feedback about your instances if you are having problems with an instance whose status is not shown as impaired, or to send AWS additional details about the problems you are experiencing with an impaired instance.

We use reported feedback to identify issues impacting multiple customers, but do not respond to individual account issues reported via this form. Providing feedback does not change the status check results that you currently see for this instance.

If you are in need of technical assistance specific to your account, please post your question to the Developer Forums or contact Premium Support.
Amazon EC2 Console

To report status feedback using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Instances.
3. On the Instances page, click on the instance on which you want to report status.
4. Click the Status Checks tab, and then click Submit feedback.
5. Complete the information on the Report Instance Status page.

Command Line Interface

Use the report-instance-status command to send status feedback using the command line interface.
The command uses the following syntax:

```
aws ec2 report-instance-status [--instances ...] [--status ...] [--reason-codes] ..
```

For more information about using the report-instance-status command, see the
report-instance-status command in the AWS Command Line Interface Reference.

API

You can use the ReportInstanceStatus action to submit feedback about a running instance’s status.
If your experience with the instance differs from the instance status returned by the
DescribeInstanceStatus action, use ReportInstanceStatus to report your experience with the
instance. Amazon EC2 collects this information to improve the accuracy of status checks. For more
information, see ReportInstanceStatus in the Amazon Elastic Compute Cloud API Reference.

Creating and Editing Status Check Alarms

You can create instance status and system status alarms to notify you when an instance has a failed
status check. To create or change these alarms, you can use either the AWS Management Console or
the command line interface (CLI).

AWS Management Console

To create a status check alarm

You can create status check alarms for an existing instance to monitor instance status or system status.
You can configure the alarm to send you a notification by email when an instance fails an instance check
or system status check.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Instances.
3. Select an instance, and then on the Status Checks tab, click Create Status Check Alarm.
4. In the Create Alarm dialog box, select the Send a notification to check box, and then choose an
existing Amazon Simple Notification Service (SNS) topic or create a new SNS topic to use for this
alarm.
5. In the With these recipients box, type your email address (e.g., john.stiles@example.com) and the
addresses of any additional recipients, separated by commas.
6. In the Whenever drop-down list, select the status check you want to be notified about (e.g., Status
Check Failed (Any), Status Check Failed (Instance), or Status Check Failed (System)).
7. In the **For at least** box, set the number of periods you want to evaluate (for example, 2) and in the **consecutive periods** drop-down menu, select the evaluation period duration (for example, 5 minutes) before triggering the alarm and sending an email.

8. To change the default name for the alarm, in the **Name of alarm** box, type a friendly name for the alarm (for example, StatusCheckFailed), and then click **Create Alarm**.

**Important**

If you added an email address to the list of recipients or created a new topic, Amazon SNS will send a subscription confirmation email message to each new address shortly after you create an alarm. Remember to click the link contained in that message, which confirms your subscription. Alert notifications are sent only to confirmed addresses.

---

**To edit a status check alarm**

If you need to make changes to an instance status alarm, you can edit it.

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, click **Instances**.
3. Select an instance, click **Actions**, and then click **Add/Edit Alarms**.
4. In the **Alarm Details** dialog box, click the name of the alarm.
5. In the **Edit Alarm** dialog box, make the desired changes, and then click **Save**.

---

**Command Line Interface**

**To create a status check alarm using the CLI**

You can create a status check alarm using the AWS CLI. In the following example, the alarm publishes a notification to a specific SNS topic that has the ARN `arn:aws:sns:us-east-1:1111111111:StatusCheckNotifications` when instance `i-ab12345` fails either the instance check or system status check for at least two periods. (The metric is StatusCheckFailed.) For more information, see the `put-metric-alarm` command in the *AWS Command Line Interface Reference*.

1. At a command prompt, type `aws cloudwatch list-metrics` to view the list of all available Amazon CloudWatch metrics for the services in AWS that you're using.
2. In the list of metrics, review the Status Check metrics that have the `AWS/EC2` namespace. These are the status check metrics that you can use to create a status check alarm.
3. At the command prompt, enter the following command:

   ```bash
   aws cloudwatch put-metric-alarm --alarm-name StatusCheckFailed-Alarm-for-i-ab12345 --alarm-description "Alarm when StatusCheckFailed metric has a value of one for two periods" --metric-name StatusCheckFailed --namespace AWS/EC2 --statistic Maximum --dimensions Name=InstanceId,Value=i-ab12345 --period 300 --unit Count --evaluation-periods 2 --threshold 1 --comparison-operator GreaterThanThreshold --alarm-actions arn:aws:sns:us-east-1:1111111111:StatusCheckNotifications
   ```

   Where:

   The **--alarm-name** is the name of the alarm. This is required.

   The **--alarm-description** is a friendly description of the alarm.

   The **--metric-name** is one of the available status metrics (e.g., StatusCheckFailed, StatusCheckFailed_Instance, or StatusCheckFailed_System). This is required.
The --namespace is the metric's namespace (e.g., AWS/EC2). This is required.

The --statistic is one of the following values: Average, Sum, Minimum, or Maximum. This is required.

The --dimensions are associated with the metric (e.g., InstanceId=i-ab12345).

The --period is the time frame (in seconds) in which Amazon CloudWatch metrics are collected. In this example, you would enter 300, which is 60 seconds multiplied by 5 minutes. This is required.

The --unit is for the alarm's associated metric.

The --evaluation-periods is the number of consecutive periods for which the value of the metric must be compared to the threshold. This is required.

The --threshold is the value to which the metric will be compared (e.g., 1). This is required.

The --alarm-actions is the list of actions to perform when this alarm is triggered. Each action is specified as an Amazon Resource Number (ARN). In this example, we want the alarm to send us an email using Amazon SNS.

Note
You can find the ARN for the Amazon SNS topic that the alarm will use in the Amazon SNS console:

1. Open the Amazon SNS console at https://console.aws.amazon.com/sns/.
2. In the navigation pane, under My Topics, select the topic you want the alarm to send mail to.
3. The ARN is located in the Topic ARN field on the Topic Details pane.

The --unit is the unit of the metric on which to alarm (e.g., Count).

Monitoring Events for Your Instances

Instance status describes specific events that AWS may schedule for your instances, such as a reboot or retirement. These scheduled events are not frequent. If one of your instances will be affected by a scheduled event, you'll receive an email prior to the scheduled event with details about the event, as well as a start and end date. You can also view scheduled events for your instance by using the Amazon EC2 console, API, or CLI. For more information, see Viewing Scheduled Events (p. 362).

There are different types of scheduled events:

- **Reboot**: A reboot can be either an instance reboot or a system reboot.
- **System maintenance**: An instance may be temporarily affected by network maintenance or power maintenance.
- **Instance retirement**: An instance that's scheduled for retirement will be stopped or terminated.
- **Instance stop**: An instance may need to be stopped in order to migrate it to new hardware.

If one of your instances is scheduled for any of the above events, you may be able to take actions to control the timing of the event, or to minimize downtime. For more information, see Working with an Instance That Has a Scheduled Event (p. 362).

Topics

- Viewing Scheduled Events (p. 362)
- Working with an Instance That Has a Scheduled Event (p. 362)
Viewing Scheduled Events

You can view scheduled events for your instances using the Amazon EC2 console, the command line interface (CLI), or the API.

Amazon EC2 Console

To view scheduled events for your instances using the console
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Events. You can see a list of all resources with events associated with them. You can filter by instance or volume, or by specific status types.
3. Alternatively, you can do the following to view upcoming scheduled events:
   a. In the navigation pane, click the EC2 Dashboard.
   b. Under Scheduled Events, you can see the events associated with your Amazon EC2 instances and volumes.

Command Line Interface and API

To view the status of your instances, use the ec2-describe-instance-status command, or the DescribeInstanceStatus API action.

Working with an Instance That Has a Scheduled Event

This section discusses tasks you can perform if your instance has a scheduled event. For all scheduled events, your course of action will differ depending on whether your instance’s root device volume is an Amazon EBS volume or an instance store volume. You can determine the root device type for an instance by checking the value of the Root device type field in the details pane on the Instances page.

Instances Scheduled for Reboot

AWS may schedule instances for a reboot in order to perform tasks such as applying patches, upgrades, or maintenance to the underlying host. There are two types of reboot events: system reboot and instance reboot. During a system reboot, your instance and the hardware supporting your instance is rebooted. During an instance reboot, your instance is rebooted, but the hardware supporting your instance is not rebooted.

Scheduled reboot events start within their scheduled maintenance window and typically complete in a matter of minutes. After a reboot completes, your instance is available to use; it is not necessary to wait until the scheduled end time.

To verify that the reboot has occurred, check your scheduled events and verify that the instance no longer shows a scheduled event. We recommend that you check your instance after it is rebooted to ensure that your application is functioning as you expected.

Actions Required for Instances Scheduled for Reboot

No action is required on your part if one of your instances is scheduled for reboot. We recommend that you wait for the reboot to occur automatically within its scheduled maintenance window.

If you choose, you may perform the reboot yourself to control the timing of the event.

Instance Reboot
For instance reboot events, you can perform the reboot yourself (be careful to not shut down or terminate your instance) at any time before the scheduled reboot event begins. For more information, see Reboot Your Instance (p. 322). After you reboot, any pending maintenance to the underlying host is performed automatically, and you can begin using your instance again after the instance has fully booted.

**Note**
After you perform the reboot, the scheduled event for the instance reboot is canceled immediately. The event's description is updated in the Amazon EC2 console to reflect this.

### System Reboot

If your instance's root device is an Amazon EBS volume, you can stop and start it. For more information, see Stop and Start Your Instance (p. 319). If your instance's root device is an instance store volume, you can terminate it and launch a replacement.

**Important**
Any data stored on an instance store volume is lost when the instance is stopped or terminated, and cannot be recovered. This includes instance store volumes that are attached to an instance that has an Amazon EBS volume as the root device.

### Instances Scheduled to Be Stopped or Retired

An instance is scheduled to be stopped or retired when AWS detects irreparable failure of the underlying hardware hosting your instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS. If your instance's root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. If your instance's root device is an instance store volume, the instance is terminated, and cannot be used again.

**Actions Required for Instances Scheduled to Be Stopped or Retired**

If your instance's root device is an Amazon EBS volume, you can wait for the instance to be stopped or retired at the scheduled event start time. Alternatively, you can stop and start the instance yourself. Doing so migrates your instance to new hardware and help reduce unforeseen downtime. For more information about stopping your instance, as well as information about changes to your instance configuration when it's stopped, see Stop and Start Your Instance (p. 319).

If your instance's root device is an instance store volume, we recommend that you launch a replacement instance from your most recent AMI, and migrate all necessary data to the replacement instance before the scheduled retirement. You can then terminate the instance, or wait for it to be automatically terminated when it's retired.

For more information about instances scheduled for retirement and how to manage them, see Instance Retirement (p. 322).

**Important**
Any data stored on instance store volumes is lost when the instance is stopped or terminated, and cannot be recovered. This includes instance store volumes that are attached to an instance that has an Amazon EBS volume as the root device. Before the instance is stopped or terminated, ensure you retrieve any data from the instance store volume that you will need later.

### Instances Scheduled for Maintenance

Instances are scheduled for maintenance when underlying Amazon EC2 hardware requires maintenance. There are two types of maintenance events: network maintenance and power maintenance. During network maintenance, scheduled instances lose network connectivity for a brief period of time. Normal network connectivity to your instance will be restored after maintenance is complete. During power maintenance, scheduled instances are offline for a brief period, and then rebooted.

**Actions Required for Instances Scheduled for Maintenance**
No action is required on your part if one of your instances is scheduled for maintenance. However, if you want to maintain normal operation during this time, you can launch a replacement instance from your most recent AMI, and migrate all necessary data to the replacement instance before the scheduled maintenance. Replacement instances are not affected by the same scheduled network or power maintenance.

For power maintenance, when a reboot is performed, all of your instance's configuration settings are retained.

Monitoring Your Instances with CloudWatch

You can monitor your Amazon EC2 instances using Amazon CloudWatch, which collects and processes raw data from Amazon EC2 into readable, near real-time metrics. These statistics are recorded for a period of two weeks, so that you can access historical information and gain a better perspective on how your web application or service is performing. By default, Amazon EC2 metric data is automatically sent to CloudWatch in 5-minute periods. You can, however, enable detailed monitoring on an Amazon EC2 instance, which sends data to CloudWatch in 1-minute periods. For more information about Amazon CloudWatch, see the Amazon CloudWatch Developer Guide.

The following table describes basic and detailed monitoring for Amazon EC2 instances.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic</td>
<td>Data is available automatically in 5-minute periods at no charge.</td>
</tr>
<tr>
<td>Detailed</td>
<td>Data is available in 1-minute periods at an additional cost. To get this level of data, you must specifically enable it for the instance. For the instances where you've enabled detailed monitoring, you can also get aggregated data across groups of similar instances. For information about pricing, see the Amazon CloudWatch product page.</td>
</tr>
</tbody>
</table>

You can get monitoring data for your Amazon EC2 instances using either the Amazon CloudWatch API or the AWS Management Console. The console displays a series of graphs based on the raw data from the Amazon CloudWatch API. Depending on your needs, you might prefer to use either the data from the API or the graphs in the console.

Enabling or Disabling Detailed Monitoring on an Amazon EC2 Instance

This section describes how to enable or disable detailed monitoring on either a new instance (as you launch it) or on a running or stopped instance. After you enable detailed monitoring, the Amazon EC2 console displays monitoring graphs with a 1-minute period for the instance. You can enable or disable detailed monitoring using the console or the command line interface (CLI).

AWS Management Console

To enable detailed monitoring of an existing EC2 instance

You can enable detailed monitoring of your EC2 instances, which provides data about your instance in 1-minute periods. (There is an additional charge for 1-minute monitoring.) Detailed data is then available for the instance in the AWS Management Console graphs or through the API. To get this level of data, you must specifically enable it for the instance. For the instances on which you’ve enabled detailed monitoring, you can also get aggregated data across groups of similar instances. An instance must be running or stopped to enable detailed monitoring.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Instances.
3. In the list of instances, select a running or stopped instance, click Actions, and then click Enable Detailed Monitoring.
4. In the Enable Detailed Monitoring dialog box, click Yes, Enable.
5. In the Enable Detailed Monitoring confirmation dialog box, click Close.

Detailed data (collected with a 1-minute period) is then available for the instance in the AWS Management Console graphs or through the API.

To enable detailed monitoring when launching an EC2 instance

• When launching an instance with the AWS Management Console, select the Monitoring check box on the Configure Instance Details page of the launch wizard.

After the instance is launched, you can select the instance in the console and view its monitoring graphs on the instance’s Monitoring tab in the lower pane.

To disable detailed monitoring of an EC2 instance

When you no longer want to monitor your instances at 1-minute intervals, you can disable detailed monitoring and use basic monitoring instead. Basic monitoring provides data in 5-minute periods at no charge.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Instances.
3. In the list of instances, select a running or stopped instance, click Actions, and then click Disable Detailed Monitoring.
4. In the Disable Detailed Monitoring dialog box, click Yes, Disable.
5. In the Disable Detailed Monitoring confirmation dialog box, click Close.

For information about launching instances, see Launch Your Instance (p. 300).
Command Line Interface

To enable detailed monitoring on an existing instance

- Use the `monitor-instances` command with one or more instance IDs. For more information about using the `monitor-instances` command, see `monitor-instances` in the AWS Command Line Interface Reference.

```bash
PROMPT> aws ec2 monitor-instances --instance-ids i-570e5a28
{
   "InstanceMonitorings": [
      {
         "InstanceId": "i-570e5a28",
         "Monitoring": {
            "State": "pending"
         }
      }
   ]
}
```

Detailed data (collected with a 1-minute period) is then available for the instance in the AWS Management Console graphs or through the API.

To enable detailed monitoring when launching an instance

- Use the `run-instances` command with the `--monitoring` flag. For more information about using the `run-instances` command, see `run-instances` in the AWS Command Line Interface Reference.

```bash
PROMPT> aws ec2 run-instances --image-id ami-09092360 --key-name MyKeyPair --monitoring Enabled=value
```

Amazon EC2 returns output similar to the following example. The status of monitoring is listed as `pending`.

```json
{
   "OwnerId": "111122223333",
   "ReservationId": "r-25fad905",
   "Groups": [
      {
         "GroupName": "default",
         "GroupId": "sg-eafe1b82"
      }
   ],
   "Instances": [
      {
         "Monitoring": {
            "State": "pending"
         },
         "PublicDnsName": null,
         "Platform": "windows",
         "State": {
            "Code": 0,
            "Name": "pending"
         },
         "EbsOptimized": false,
      }
   ]
}
```
After the instance is running, detailed data (collected with a 1-minute period) is then available for the instance in the AWS Management Console graphs or through the API.

To disable detailed monitoring of an instance

- Use the `unmonitor-instances` command with one or more instance IDs. For more information about using the `unmonitor-instances` command, see `unmonitor-instances` in the AWS Command Line Interface Reference.

PROMPT> `aws ec2 unmonitor-instances --instance-ids i-570e5a28`

```json
{
   "InstanceMonitorings": [
   {
      "InstanceId": "i-570e5a28",
      "Monitoring": {
         "State": "disabling"
      }
   }
   ]
}
```
View Amazon EC2 Metrics

Only those services in AWS that you're using send metrics to Amazon CloudWatch. You can use the Amazon CloudWatch console, the `mon-list-metrics` command, or the `ListMetrics` API to view the metrics that Amazon EC2 sends to CloudWatch. If you've enabled detailed monitoring, each data point covers the instance's previous 1 minute of activity. Otherwise, each data point covers the instance’s previous 5 minutes of activity.

### AWS Management Console

To view available metrics by category

You can view metrics by category. Metrics are grouped first by Namespace, and then by the various Dimension combinations within each Namespace. For example, you can view all EC2 metrics, or EC2 metrics grouped by instance ID, instance type, image (AMI) ID, or Auto Scaling Group.

1. Open the Amazon CloudWatch console at [https://console.aws.amazon.com/cloudwatch/](https://console.aws.amazon.com/cloudwatch/).
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see [Regions and Endpoints](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/regions.html).
3. In the navigation pane, click **Metrics**.
4. In the CloudWatch Metrics by Category pane, under EC2 Metrics, select Per-Instance Metrics, and then in the upper pane, scroll down to view the full list of metrics.

Command Line Interface

To list available metrics across multiple Amazon EC2 instances

- Enter the `list-metrics` command and specify the AWS/EC2 namespace to limit the results to Amazon EC2. For more information about the `list-metrics` command, see `list-metrics` in the AWS Command Line Interface Reference.

`Prompt> aws cloudwatch list-metrics --namespace AWS/EC2`
CloudWatch returns the following (partial listing):

```json
{
    "Namespace": "AWS/EC2",
    "Dimensions": [
        {
            "Name": "InstanceType",

Get Statistics for Metrics

This set of scenarios shows you how you can use the AWS Management Console, the `get-metric-statistics` command, or the `GetMetricStatistics` API to get a variety of statistics.

**Note**
Start and end times must be within the last 14 days.

**Topics**
- Get Statistics for a Specific EC2 Instance (p. 374)
- Aggregating Statistics Across Instances (p. 378)
- Get Statistics Aggregated by Auto Scaling Group (p. 383)
- Get Statistics Aggregated by Image (AMI) ID (p. 385)
Get Statistics for a Specific EC2 Instance

The following scenario walks you through how to use the AWS Management Console or the `get-metric-statistics` command to determine the maximum CPU utilization of a specific EC2 instance.

**Note**
Start and end times must be within the last 14 days.

For this example, we assume that you have an EC2 instance ID. You can get an active EC2 instance ID through the AWS Management Console or with the `describe-instances` command.

**AWS Management Console**

To display the average CPU utilization for a specific instance

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints.

3. In the navigation pane, click Metrics.
4. In the CloudWatch Metrics by Category pane, select EC2: Metrics.

   The metrics available for individual instances appear in the upper pane.
5. Select a row that contains CPUUtilization for a specific InstanceId.

   A graph showing average CPUUtilization for a single instance appears in the details pane.
6. To change the **Statistic**, e.g., Average, for the metric, choose a different value from the pop-up list.

7. To change the **Period**, e.g., 5 Minutes, to view data in more granular detail, choose a different value from the pop-up list.
Command Line Interface

To get the CPU utilization per EC2 instance

- Enter the `get-metric-statistics` command with the following parameters. For more information about the `get-metric-statistics` command, see `get-metric-statistics` in the AWS Command Line Interface Reference.

```
aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-time 2014-02-18T23:18:00 --end-time 2014-02-19T23:18:00 --period 3600 --namespace AWS/EC2 --statistics Maximum --dimensions Name=InstanceId,Value=<your-instance-id>
```

The AWS CLI returns the following:

```
{

The returned statistics are six-minute values for the requested two-day time interval. Each value represents the maximum CPU utilization percentage for a single EC2 instance.

### Aggregating Statistics Across Instances

Aggregate statistics are available for the instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. In addition, Amazon CloudWatch does not aggregate data across Regions. Therefore, metrics are completely separate between Regions. Before you can get statistics aggregated across instances, you must enable detailed monitoring (at an additional charge), which provides data in 1-minute periods. This scenario shows you how to use detailed monitoring with either the AWS Management Console, the `GetMetricStatistics` API, or the `get-metric-statistics` command to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the `AWS/EC2` namespace. To get statistics for other metrics, see Amazon CloudWatch Namespaces, Dimensions, and Metrics Reference.

**Important**

This technique for retrieving all dimensions across an AWS namespace does not work for custom namespaces that you publish to Amazon CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

### AWS Management Console

**To display average CPU utilization for your Amazon EC2 instances**

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints.
3. In the navigation pane, click Metrics.
4. In the CloudWatch Metrics by Category pane, under EC2 Metrics, select Across All Instances.
The metrics available across all instances are displayed in the upper pane.

5. In the upper pane, select the row that contains **CPUUtilization**.

A graph showing **CPUUtilization** for your EC2 instances is displayed in the details pane.

6. To change the **Statistic**, e.g., Average, for the metric, choose a different value from the pop-up list.
7. To change the Period, e.g., 5 Minutes, to view data in more granular detail, choose a different value from the pop-up list.

Command Line Interface

To get average CPU utilization across your Amazon EC2 instances

- Enter the `get-metric-statistics` command with the following parameters. For more information about the `get-metric-statistics` command, see `get-metric-statistics` in the AWS Command Line Interface Reference.

```
Prompt> aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-time 2014-02-11T23:18:00 --end-time 2014-02-12T23:18:00 --period 3600 --namespace AWS/EC2 --statistics "Average" "SampleCount"
```

The AWS CLI returns the following:

```json
{
   "Datapoints": [
      {
         "SampleCount": 238.0,
         "Timestamp": "2014-02-12T07:18:00Z",
         "Average": 0.038235294117647062,
         "Unit": "Percent"
      },
      {

Get Statistics Aggregated by Auto Scaling Group

This scenario shows you how to use the AWS Management Console, the `get-metric-statistics` command, or the `GetMetricStatistics` API with the `DiskWriteBytes` metric to retrieve the total bytes written to disk for one Auto Scaling group. The total is computed for one-minute periods for a 24-hour interval across all EC2 instances in the specified `AutoScalingGroupName`.

**Note**

Start and end times must be within the last 14 days.

We assume for this example that an EC2 application is running and has an Auto Scaling group named `test-group-1`.

**AWS Management Console**

**To display total DiskWriteBytes for an Auto-Scaled EC2 application**

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints.
3. In the navigation pane, click Metrics.
4. In the CloudWatch Metrics by Category pane, under EC2 Metrics, select By Auto Scaling Group.
   The metrics available for Auto Scaling groups are displayed in the upper pane.
5. Select the row that contains DiskWriteBytes.
   A graph showing DiskWriteBytes for all EC2 instances appears in the details pane.
6. To change the **Statistic**, e.g., *Average*, for the metric, choose a different value from the pop-up list.

7. To change the **Period**, e.g., *5 Minutes*, to view data in more granular detail, choose a different value from the pop-up list.
**Command Line Interface**

**To get total DiskWriteBytes for an auto-scaled EC2 application**

- Enter the `get-metric-statistics` command with the following parameters. For more information about the `get-metric-statistics` command, see `get-metric-statistics` in the [AWS Command Line Interface Reference](https://aws.amazon.com/documentation/).

```bash
prompt> aws cloudwatch get-metric-statistics --metric-name DiskWriteBytes --start-time 2014-02-16T23:18:00 --end-time 2014-02-18T23:18:00 --period 360 --namespace AWS/EC2 --statistics "Sum" "SampleCount" --dimensions Name=AutoScalingGroupName,Value=test-group-1
```

The AWS CLI returns the following:

```json
{
  "Datapoints": [
    {
      "SampleCount": 18.0,
      "Timestamp": "2014-02-19T21:36:00Z",

**Get Statistics Aggregated by Image (AMI) ID**

This scenario shows you how to use the AWS Management Console, the `get-metric-statistics` command, or the `GetMetricStatistics` API to determine average CPU utilization for all instances that match a given image ID. The average is over 60-second time intervals for a one-day period.

**Note**

Start and end times must be within the last 14 days.

In this scenario, the EC2 instances are running an image ID of `ami-c5e40dac`.

**AWS Management Console**

**To display the average CPU utilization for an image ID**

1. Open the Amazon CloudWatch console at [https://console.aws.amazon.com/cloudwatch/](https://console.aws.amazon.com/cloudwatch/).
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see [Regions and Endpoints](https://aws.amazon.com/documentation/).
3. In the navigation pane, click Metrics.

4. In the CloudWatch Metrics by Category pane, under EC2 Metrics, select By Image (AMI) Id.

   The metrics available for image IDs appear in the upper pane.

5. Select a row that contains CPUUtilization and an image ID.

   A graph showing average CPUUtilization for all EC2 instances based on the ami-c5e40dac image ID appears in the details pane.

6. To change the Statistic, e.g., Average, for the metric, choose a different value from the pop-up list.
7. To change the Period, e.g., 5 Minutes, to view data in more granular detail, choose a different value from the pop-up list.

**Command Line Interface**

**To get the average CPU utilization for an image ID**

- Enter the `get-metric-statistics` command as in the following example. For more information about the `get-metric-statistics` command, see `get-metric-statistics` in the AWS Command Line Interface Reference.

```
prompt> aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-time 2014-02-10T00:00:00 --end-time 2014-02-11T00:00:00 --period 3600 --statistics Average --namespace AWS/EC2 --dimensions Name="ImageId",Value="ami-3c47a355"
```

The AWS CLI returns the following:

```json
{   "Datapoints": [       {           "Timestamp": "2014-02-10T07:00:00Z",           "Average": 0.041000000000000009,           "Unit": "Percent"       },       {           "Timestamp": "2014-02-10T14:00:00Z",           "Average": 0.079579831932773085,           "Unit": "Percent"       }   ]}

"Label": "CPUUtilization"}
The operation returns statistics that are one-minute values for the one-day interval. Each value represents an average CPU utilization percentage for EC2 instances running the specified machine image.

**Graphing Metrics**

After you launch an instance, you can go to the Amazon EC2 console and view the instance’s monitoring graphs. They’re displayed when you select the instance on the Instances page in the EC2 Dashboard. A Monitoring tab is displayed next to the instance’s Description tab. The following graphs are available:

- Average CPU Utilization (Percent)
- Average Disk Reads (Bytes)
- Average Disk Writes (Bytes)
- Maximum Network In (Bytes)
- Maximum Network Out (Bytes)
- Summary Disk Read Operations (Count)
- Summary Disk Write Operations (Count)
- Summary Status (Any)
- Summary Status Instance (Count)
- Summary Status System (Count)

You can also use the CloudWatch console to graph metric data generated by Amazon EC2 and other AWS services to make it easier to see what’s going on. You can use the following procedures to graph metrics in CloudWatch.

**Topics**

- Graph a Metric (p. 390)
- Graph a Metric Across Resources (p. 391)

**Graph a Metric**

You can select a metric and create a graph of the data in CloudWatch. For example, you can select the CPUUtilization metric for an Amazon EC2 instance and display a graph of CPU usage over time for that instance.

**To graph a metric**

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints in the Amazon Web Services General Reference.
3. In the navigation pane, click **Metrics**.

4. In the **CloudWatch Metrics by Category** pane, use the **Search Metrics** box and categories to find a metric by metric name, AWS resource, or other metadata.

5. Use the scroll bar and next and previous arrows above the metrics list to page through the full list of metrics.

6. Select the metric to view, for example, CPUUtilization. A graph appears in the details pane.

   ![Graphing Metrics](image)

   ![Metrics List](image)

7. To save this graph and access it later, in the details pane, under **Tools**, click **Copy URL**, and then in the **Copy Graph URL** dialog box, select the URL and paste it into your browser.

### Graph a Metric Across Resources

You can graph a metric across all resources to see everything on one graph. For example, you can graph the CPUUtilization metric for all Amazon EC2 instances on one graph.

#### To graph a metric across resources

1. Open the Amazon CloudWatch console at [https://console.aws.amazon.com/cloudwatch/](https://console.aws.amazon.com/cloudwatch/).
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see **Regions and Endpoints**.
3. In the navigation pane, click **Metrics**.

4. In the **CloudWatch Metrics by Category** pane, select a metric category. For example, under **EC2 Metrics**, select **Per-Instance Metrics**.
5. In the metric list, in the Metric Name column, click a metric. For example CPUUtilization.

6. At the top of the metric list, click Select All.

The graph shows all data for all occurrences of the selected metric. In the example below, CPUUtilization for all Amazon EC2 instances is shown.

7. To save this graph and access it later, in the details pane, under Tools, click Copy URL, and then in the Copy Graph URL dialog box, select the URL and paste it into your browser.
Create a CloudWatch Alarm

You can create an Amazon CloudWatch alarm that monitors any one of your Amazon EC2 instance’s CloudWatch metrics. CloudWatch will automatically send you a notification when the metric reaches a threshold you specify. You can create a CloudWatch alarm on the Amazon EC2 console of the AWS Management Console, or you can use the CloudWatch console and configure more advanced options.

Send Email Based on CPU Usage Alarm

This scenario walks you through how to use the AWS Management Console or the command line interface to create an Amazon CloudWatch alarm that sends an Amazon Simple Notification Service email message when the alarm changes state from OK to ALARM.

In this scenario, you configure the alarm to change to the ALARM state when the average CPU use of an EC2 instance exceeds 70 percent for two consecutive five-minute periods.

Topics
  • AWS Management Console (p. 394)
  • Command Line Interface (p. 396)

AWS Management Console

To create an alarm that sends email based on CPU usage

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints.

3. In the navigation pane, click Alarms.
4. Click Create Alarm, and then in CloudWatch Metrics by Category, select a metric category, for example, EC2 Metrics.
5. In the list of metrics, select a row that contains CPUUtilization for a specific instance ID.

A graph showing average CPUUtilization for a single instance appears in the lower pane.
6. Select **Average** from the **Statistic** drop-down list.
7. Select a period from the **Period** drop-down list, for example: **5 minutes**.
8. Click **Next**, and then under **Alarm Threshold**, in the **Name** field, enter a unique name for the alarm, for example: **myHighCpuAlarm**.
9. In the **Description** field, enter a description of the alarm, for example: **CPU usage exceeds 70 percent**.
10. In the **is** drop-down list, select **>**.
11. In the box next to the **is** drop-down list, enter **70** and in the **for** field, enter **10**.

   A graphical representation of the threshold is shown under **Alarm Preview**.
12. Under **Actions**, in the **Whenever this alarm** drop-down list, select **State is ALARM**.
13. In the **Send notification to** drop-down list, select an existing Amazon SNS topic or create a new one.
14. To create a new Amazon SNS topic, select **New list**.

   In the **Send notification to** field, enter a name for the new Amazon SNS topic for example: **myHighCpuAlarm**, and in the **Email list** field, enter a comma-separated list of email addresses to be notified when the alarm changes to the **ALARM** state.
15. Click **Create Alarm** to complete the alarm creation process.
Command Line Interface

To send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent

1. Set up an Amazon Simple Notification Service topic or retrieve the Topic Resource Name of the topic you intend to use. For help on setting up an Amazon Simple Notification Service topic, see Set Up Amazon Simple Notification Service.

2. Create an alarm with the put-metric-alarm command. For more information about the put-metric-alarm command, see put-metric-alarm in the AWS Command Line Interface Reference. Use the values from the following example, but replace the values for InstanceID and alarm-actions with your own values.

```
Prompt> aws cloudwatch
    put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm when CPU exceeds 70%" --metric-name CPUUtilization --namespace AWS/EC2 --statistic Average --period 300 --threshold 70 --comparison-operator GreaterThanThreshold --dimensions Name=InstanceId,Value=i-12345678 --evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:11112223333:MyTopic --unit Percent
```

The AWS CLI returns to the command prompt if the command succeeds.

3. Test the alarm by forcing an alarm state change with the set-alarm-state command.

   a. Change the alarm state from INSUFFICIENT_DATA to OK:

```
Prompt> aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason "initializing" --state-value OK
```

The AWS CLI returns to the command prompt if the command succeeds.

   b. Change the alarm state from OK to ALARM:

```
Prompt> aws cloudwatch set-alarm-state --alarm-name cpu-mon --state-reason "initializing" --state-value ALARM
```

The AWS CLI returns to the command prompt if the command succeeds.

   c. Check that an email has been received.

Send Email Based on Load Balancer Alarm

This scenario walks you through how to use the AWS Management Console or the command line interface to set up an Amazon Simple Notification Service notification and configure an alarm that monitors load balancer latency exceeding 100 ms.

Topics

- AWS Management Console (p. 397)
- Command Line Interface (p. 398)
AWS Management Console

To create a load balancer alarm that sends email

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints.

3. In the navigation pane, click Alarms.
4. Click Create Alarm, and then in the CloudWatch Metrics by Category pane, select a metric category, for example, ELB Metrics.
5. In the list of metrics, select a row that contains Latency for a specific load balancer.

A graph showing average Latency for a single load balancer appears in the lower pane.
6. Select **Average** from the **Statistic** drop-down list.
7. Select **1 Minute** from the **Period** drop-down list.
8. Click **Next**, and then under **Alarm Threshold**, in the **Name** field, enter a unique name for the alarm, for example: myHighCpuAlarm.
9. In the **Description** field, enter a description of the alarm, for example: **Alarm when Latency exceeds 100ms**.
10. In the **is** drop-down list, select >.
11. In the box next to the **is** drop-down list, enter 0.1 and in the **for** field, enter 3.

A graphical representation of the threshold is shown under **Alarm Preview**.
12. Under **Actions**, in the **Whenever this alarm** drop-down list, select **State is ALARM**.
13. In the **Send notification to** drop-down list, select an existing Amazon SNS topic or create a new one.
14. To create a new Amazon SNS topic, select **New list**.
   In the **Send notification to** field, enter a name for the new Amazon SNS topic for example: myHighCpuAlarm, and in the **Email list** field, enter a comma-separated list of email addresses to be notified when the alarm changes to the **ALARM** state.
15. Click **Create Alarm** to complete the alarm creation process.

**Command Line Interface**

**To send an Amazon Simple Notification Service email message when LoadBalancer Latency Exceeds 100 milliseconds**

1. Create an Amazon Simple Notification Service topic. See instructions for creating an Amazon SNS topic in Set Up Amazon Simple Notification Service.
2. Use the **put-metric-alarm** command to create an alarm. For more information about the **put-metric-alarm** command, see **put-metric-alarm** in the AWS Command Line Interface Reference.

```bash
Prompt> aws cloudwatch put-metric-alarm --alarm-name lb-mon --alarm-description "Alarm when Latency exceeds 100ms" --metric-name Latency --namespace AWS/ELB --statistic Average --period 60 --threshold 100 --comparison-operator GreaterThanThreshold --dimensions Name=LoadBalancerName,Value=my-server --evaluation-periods 3 --alarm-actions arn:aws:sns:us-east-1:1234567890:my-topic --unit Milliseconds

The AWS CLI returns to the command prompt if the command succeeds.
3. Test the alarm.

• Force an alarm state change to ALARM:

```bash
Prompt> aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason "initializing" --state OK
Prompt> aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason "initializing" --state ALARM

The AWS CLI returns to the command prompt if the command succeeds.
• Check that an email has been received.
Send Email Based on Storage Throughput Alarm

This scenario walks you through how to use the AWS Management Console or the command line interface to set up an Amazon Simple Notification Service notification and to configure an alarm that sends email when EBS exceeds 100 MB throughput.

Topics

• AWS Management Console (p. 399)
• Command Line Interface (p. 401)

AWS Management Console

To create a storage throughput alarm that sends email

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region that meets your needs. For more information, see Regions and Endpoints.
3. In the navigation pane, click Alarms.
4. Click Create Alarm, and then in the CloudWatch Metrics by Category pane, select a metric category, for example, EBS Metrics.
5. In the list of metrics, select a row that contains VolumeWriteBytes for a specific VolumeId.

A graph showing average VolumeWriteBytes for a single volume appears in the lower pane.
6. Select Average from the Statistic drop-down list.
7. Select 5 Minutes from the Period drop-down list.
8. Click Next, and then under Alarm Threshold, in the Name field, enter a unique name for the alarm, for example: myHighWriteAlarm.
9. In the Description field, enter a description of the alarm, for example: VolumeWriteBytes exceeds 100,000 KiB/s.
10. In the is drop-down list, select >.
11. In the box next to the is drop-down list, enter 100000 and in the for field, enter 15.

A graphical representation of the threshold is shown under Alarm Preview.
12. Under Actions, in the Whenever this alarm drop-down list, select State is ALARM.
13. In the Send notification to drop-down list, select an existing Amazon SNS topic or create a new one.
14. To create a new Amazon SNS topic, select New list.

In the Send notification to field, enter a name for the new Amazon SNS topic for example: myHighCpuAlarm, and in the Email list field, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state.
15. Click Create Alarm to complete the alarm creation process.
Command Line Interface

To send an Amazon Simple Notification Service email message when EBS exceeds 100 MB throughput

1. Create an Amazon Simple Notification Service topic. See instructions for creating an Amazon SNS topic in Set Up Amazon Simple Notification Service.
2. Use the `put-metric-alarm` command to create an alarm. For more information about the `put-metric-alarm` command, see `put-metric-alarm` in the AWS Command Line Interface Reference.

```bash
```

The AWS CLI returns to the command prompt if the command succeeds.
3. Test the alarm.

- Force an alarm state change to ALARM.

```bash
Prompt> aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason "initializing" --state-value OK
Prompt> aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason "initializing" --state-value ALARM
Prompt> aws cloudwatch set-alarm-state --alarm-name lb-mon --state-reason "initializing" --state-value INSUFFICIENT_DATA
```

- Check that two emails have been received.

Create Alarms That Stop or Terminate an Instance

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop or terminate your Amazon Elastic Compute Cloud (Amazon EC2) instances when you no longer need them to be running. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than leave those instances sitting idle (and accruing charges), you can stop or terminate them which can help you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily restart a stopped instance if you need to run it again later, and you can keep the same instance ID and root volume. However, you cannot restart a terminated instance. Instead, you must launch a new instance.

You can add the stop or terminate alarm actions to any alarm that is set on an Amazon EC2 instance metric, including basic and detailed monitoring metrics provided by Amazon CloudWatch (in the AWS/EC2 namespace), as well as any custom metrics that include the “InstanceId=” dimension, as long as the InstanceId value refers to a valid running Amazon EC2 instance.

Adding Actions to Amazon CloudWatch Alarms

You can configure alarm actions using either the Amazon EC2 console or the Amazon CloudWatch console, or you can use the Amazon CloudWatch command line interface (CLI), API, or the AWS SDKs. For information about using the Amazon CloudWatch API with the AWS SDKs, see Sample Code & Libraries.

Using the Amazon EC2 Console to Create an Alarm to Stop an Instance

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an Amazon Simple Notification Service (Amazon SNS) notification, so that you will receive an email when the alarm is triggered.

Amazon EC2 instances that use an Amazon Elastic Block Store volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated.

Note
If you are using an AWS Identity and Access Management (IAM) account to create or modify an alarm, you must have the following Amazon EC2 permissions:
- ec2:DescribeInstanceStatus
- ec2:DescribeInstances
- ec2:StopInstances
- ec2:TerminateInstances

In order for the alarm action to be performed. If you have read/write permissions for Amazon CloudWatch but not for Amazon EC2, you can still create an alarm but the stop or terminate actions won’t be performed on the Amazon EC2 instance. However, if you are later granted permission to use the associated Amazon EC2 APIs, the alarm actions you created earlier will be performed. For more information about IAM permissions, see Permissions and Policies in Using IAM.

If you are using an IAM role (e.g. Amazon EC2 instance profile), you cannot stop or terminate the instance using alarm actions. However, you can still see the alarm state and perform any other actions such as Amazon SNS notifications or Auto Scaling policies.

If you are using temporary security credentials granted using the AWS Security Token Service (AWS STS), you cannot stop or terminate an Amazon EC2 instance using alarm actions.

To create an alarm to stop an idle instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. If necessary, change the region. From the navigation bar, select the region where your instance is running. For more information, see Regions and Endpoints.
3. In the navigation pane, under INSTANCES, click Instances.
4. In the upper pane, right-click an instance, and then click Add/Edit Alarms.
Or, you can also select the instance, and then in the lower pane on the Monitoring tab, click **Create Alarm**.

5. In the **Alarm Details for** dialog box, click **Create Alarm**.

6. If you want to receive an email when the alarm is triggered, in the **Create Alarm for** dialog box, in the **Send a notification to** box, select an existing Amazon SNS topic, or click **Create Topic** to create a new one.

   If you create a new topic, in the **Send a notification to** box type a name for the topic, and then in the **With these recipients** box, type the email addresses of the recipients (separated by commas). Later, after you create the alarm, you will receive a subscription confirmation email that you must accept before you will get email for this topic.

7. Select the **Take the action** check box, and then choose the **Stop** radio button.

8. In the **Whenever** boxes, choose the statistic you want to use and then select the metric. In this example, choose **Average** and **CPU Utilization**.

9. In the **Is** boxes, define the metric threshold. In this example, enter **10** percent.

10. In the **For at least** box, choose the sampling period for the alarm. In this example, enter **24** consecutive periods of one hour.

11. To change the name of the alarm, in the **Name this alarm** box, type a new name.

   If you don't type a name for the alarm, Amazon CloudWatch automatically creates one for you.
You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.

12. Click Create Alarm.

Using the Amazon EC2 Console to Create an Alarm that Terminates an Instance

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don’t need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. For information on enabling and disabling termination protection for an instance, see Enabling Termination Protection for an Instance in the Amazon Elastic Compute Cloud User Guide.

Note
If you are using an AWS Identity and Access Management (IAM) account to create or modify an alarm, you must have the following Amazon EC2 permissions:
- ec2:DescribeInstanceStatus, ec2:DescribeInstances, ec2:StopInstances, and ec2:TerminateInstances in order for the alarm action to be performed. If you have read/write permissions for Amazon CloudWatch but not for Amazon EC2, you can still create an alarm but the stop or terminate actions won’t be performed on the Amazon EC2 instance. However, if you are later granted permission to use the associated Amazon EC2 APIs, the alarm actions you created earlier will be performed. For more information about IAM permissions, see Permissions and Policies in Using IAM.
- If you are using an IAM role (e.g. Amazon EC2 instance profile), you cannot stop or terminate the instance using alarm actions. However, you can still see the alarm state and perform any other actions such as Amazon SNS notifications or Auto Scaling policies.
- If you are using temporary security credentials granted using the AWS Security Token Service (AWS STS), you cannot stop or terminate an Amazon EC2 instance using alarm actions.

To create an alarm to terminate an idle instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. If necessary, change the region. From the navigation bar, select the region where your instance is running. For more information, see Regions and Endpoints.
3. In the navigation pane, under INSTANCES, click Instances.
4. In the upper pane, right-click an instance, and then click Add/Edit Alarms.

Or, select the instance and then in the lower pane, on the Monitoring tab, click Create Alarm.
5. In the Alarm Details for dialog box, click Create Alarm.
6. If you want to receive an email when the alarm is triggered, in the Create Alarm for dialog box, in the Send a notification to box, select an existing SNS topic, or click Create Topic to create a new one.

   If you create a new topic, in the Send a notification to box type a name for the topic, and then in the With these recipients box, type the email addresses of the recipients (separated by commas). Later, after you create the alarm, you will receive a subscription confirmation email that you must accept before you will get email for this topic.

7. Select the Take the action check box, and then choose the Terminate radio button.

8. In the Whenever boxes, choose the statistic you want to use and then select the metric. In this example, choose Average and CPU Utilization.

9. In the Is boxes, define the metric threshold. In this example, enter 10 percent.

10. In the For at least box, choose the sampling period for the alarm. In this example, enter 24 consecutive periods of one hour.

11. To change the name of the alarm, in the Name this alarm box, type a new name.

   If you don't type a name for the alarm, Amazon CloudWatch automatically creates one for you.

**Note**

You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.
12. Click **Create Alarm**.

### Using the Amazon CloudWatch Console to Create an Alarm that Stops an Instance

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an Amazon Simple Notification Service (Amazon SNS) notification, so that you will receive an email when the alarm is triggered.

Amazon CloudWatch alarm actions can stop an EBS-backed Amazon EC2 instances but they cannot stop instance store-backed Amazon EC2 instances. However, Amazon CloudWatch alarm actions can terminate either type of Amazon EC2 instance.

**Note**

If you are using an AWS Identity and Access Management (IAM) account to create or modify an alarm, you must have the following Amazon EC2 permissions:
```
etc2:DescribeInstanceStatus, ec2:DescribeInstances, ec2:StopInstances, and
etc2:TerminateInstances
```
In order for the alarm action to be performed. If you have read/write permissions for Amazon CloudWatch but not for Amazon EC2, you can still create an alarm but the stop or terminate actions won’t be performed on the Amazon EC2 instance. However, if you are later granted permission to use the associated Amazon EC2 APIs, the alarm actions you created earlier will be performed. For more information about IAM permissions, see Permissions and Policies in Using IAM.

If you are using an IAM role (e.g. Amazon EC2 instance profile), you cannot stop or terminate the instance using alarm actions. However, you can still see the alarm state and perform any other actions such as Amazon SNS notifications or Auto Scaling policies.

If you are using temporary security credentials granted using the AWS Security Token Service (AWS STS), you cannot stop or terminate an Amazon EC2 instance using alarm actions.

### To create an alarm to stop an idle instance

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region where your instance is running. For more information, see Regions and Endpoints.
3. In the navigation pane, click **Alarms**.
4. Click **Create Alarm**, and then in the **CloudWatch Metrics by Category** pane, under **EC2 Metrics**, select **Per-Instance Metrics**.
5. In the list of metrics, select the instance and metric you want to create an alarm for. You can also type an instance ID in the search box to go the instance that you want.
6. Select **Average** from the **Statistic** drop-down list.
7. Select a period from the Period drop-down list, for example: 1 Day.
8. Click Next, and then under Alarm Threshold, in the Name field, enter a unique name for the alarm, for example: Stop EC2 instance.
9. In the Description field, enter a description of the alarm, for example: Stop EC2 instance when CPU is idle for too long.
10. In the is drop-down list, select <.
11. In the box next to the is drop-down list, enter 10 and in the for field, enter 1440.
   A graphical representation of the threshold is shown under Alarm Preview.
13. In the Whenever this alarm drop-down list, select State is ALARM.
14. In the Take this action drop-down list, select Stop this instance.
15. Click Notification, and then in the Send notification to drop-down list, select an existing Amazon SNS topic or create a new one.
16. To create a new Amazon SNS topic, select New list.
   In the Send notification to field, enter a name for the new Amazon SNS topic for example: Stop_EC2_Instance, and in the Email list field, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state.
   Important
   If you are creating a new topic or adding email addresses to an existing topic, each email address that you add will be sent a topic subscription confirmation email. You must confirm the subscription by clicking the included link before notifications will be sent to a new email address.
17. Click Create Alarm to complete the alarm creation process.

Using the Amazon CloudWatch Console to Create an Alarm to Terminate an Idle Instance

You can create an alarm that terminates an Amazon EC2 instance automatically when a certain threshold has been met, as long as termination protection is disabled on the instance. For example, you might want to terminate an instance when it has completed its work, and you don’t need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. For information on disabling termination protection on an instance, see Enabling Termination Protection for an Instance in the Amazon Elastic Compute Cloud User Guide.

Note
If you are using an AWS Identity and Access Management (IAM) account to create or modify an alarm, you must have the following Amazon EC2 permissions:
ec2:DescribeInstanceStatus, ec2:DescribeInstances, ec2:StopInstances, and ec2:TerminateInstances in order for the alarm action to be performed. If you have read/write permissions for Amazon CloudWatch but not for Amazon EC2, you can still create an alarm but the stop or terminate actions won’t be performed on the Amazon EC2 instance. However, if you are later granted permission to use the associated Amazon EC2 APIs, the alarm actions you created earlier will be performed. For more information about IAM permissions, see Permissions and Policies in Using IAM.

If you are using an IAM role (e.g. Amazon EC2 instance profile), you cannot stop or terminate the instance using alarm actions. However, you can still see the alarm state and perform any other actions such as Amazon SNS notifications or Auto Scaling policies.
If you are using temporary security credentials granted using the AWS Security Token Service (AWS STS), you cannot stop or terminate an Amazon EC2 instance using alarm actions.
To create an alarm to terminate an idle instance

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region where your instance is running. For more information, see Regions and Endpoints.

3. In the navigation pane, click Alarms.
4. In the upper pane, click Create Alarm.
5. Click Create Alarm, and then in the CloudWatch Metrics by Category pane, under EC2 Metrics, select Per-Instance Metrics.
6. In the list of metrics, select the instance and metric you want to create an alarm for. You can also type an instance ID in the search box to go the instance that you want.
7. Select Average from the Statistic drop-down list.
8. Select a period from the Period drop-down list, for example: 1 Day.
9. Click Next, and then under Alarm Threshold, in the Name field, enter a unique name for the alarm, for example: Terminate EC2 instance.
10. In the Description field, enter a description of the alarm, for example: Terminate EC2 instance when CPU is idle for too long.
11. In the is drop-down list, select <.
12. In the box next to the is drop-down list, enter 10 and in the for field, enter 1440.

   A graphical representation of the threshold is shown under Alarm Preview.
14. In the Whenever this alarm drop-down list, select State is ALARM.
15. In the Take this action drop-down list, select Terminate this instance.
16. Click Notification, and then in the Send notification to drop-down list, select an existing Amazon SNS topic or create a new one.
17. To create a new Amazon SNS topic, select New list.
   In the Send notification to field, enter a name for the new Amazon SNS topic for example: Terminate_EC2_Instance, and in the Email list field, enter a comma-separated list of email addresses to be notified when the alarm changes to the ALARM state.

   Important
   If you are creating a new topic or adding email addresses to an existing topic, each email address that you add will be sent a topic subscription confirmation email. You must confirm the subscription by clicking the included link before notifications will be sent to a new email address.
18. Click Create Alarm to complete the alarm creation process.
Using the Amazon CloudWatch Console to View the History of Triggered Alarms and Actions

You can view alarm and action history in the Amazon CloudWatch console. Amazon CloudWatch keeps the last two weeks' worth of alarm and action history.

To view the history of triggered alarms and actions

1. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. If necessary, change the region. From the navigation bar, select the region where your instance is running. For more information, see Regions and Endpoints.
3. In the navigation pane, click Alarms.
4. In the upper pane, select the alarm with the history that you want to view.
5. In the lower pane, the Details tab shows the most recent state transition along with the time and metric values.
6. Click the History tab to view the most recent history entries.

Using the CLI or the API to Create an Alarm to Stop or Terminate an Instance

If you are using either the AWS CLI or the CloudWatch API, or if you are using the AWS SDKs with the API, you can create an Amazon CloudWatch alarm using an Amazon EC2 instance metric, and then add an action using the action's dedicated Amazon Resource Name (ARN). You can add the action to any alarm state, and you can specify the region for each action. The region must match the region to which you send the put-metric-alarm request.

<table>
<thead>
<tr>
<th>Action</th>
<th>ARN (with region)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop</td>
<td>arn:aws:automate:us-east-1:ec2:stop</td>
</tr>
<tr>
<td>Terminate</td>
<td>arn:aws:automate:us-east-1:ec2:terminate</td>
</tr>
</tbody>
</table>

For information about using the Amazon CloudWatch API with the AWS SDKs, see Sample Code & Libraries.

Note

If you are using an AWS Identity and Access Management (IAM) account to create or modify an alarm, you must have the following Amazon EC2 permissions:

ec2:DescribeInstanceStatus, ec2:DescribeInstances, ec2:StopInstances, and ec2:TerminateInstances in order for the alarm action to be performed. If you have read/write permissions for Amazon CloudWatch but not for Amazon EC2, you can still create an alarm but the stop or terminate actions won’t be performed on the Amazon EC2 instance. However, if you
are later granted permission to use the associated Amazon EC2 APIs, the alarm actions you created earlier will be performed. For more information about IAM permissions, see Permissions and Policies in Using IAM.

If you are using an IAM role (e.g., Amazon EC2 instance profile), you cannot stop or terminate the instance using alarm actions. However, you can still see the alarm state and perform any other actions such as Amazon SNS notifications or Auto Scaling policies.

If you are using temporary security credentials granted using the AWS Security Token Service (AWS STS), you cannot stop or terminate an Amazon EC2 instance using alarm actions.

To create an alarm to stop an instance using the CLI

You can use the arn:aws:automate:us-east-1:ec2:stop ARN to stop an Amazon EC2 instance. The following example shows how to stop an instance if the average CPUUtilization is less than 10 percent over a 24 hour period.

- At a command prompt, type:

```
% aws cloudwatch put-metric-alarm --alarm-name my-Alarm --alarm-description "Stop the instance when it is idle for a day" --dimensions Name=InstanceId,Value=i-abc123 --namespace "AWS/EC2" --statistic Average --metric-name CPUUtilization --comparison-operator LessThanThreshold --threshold 10 --period 86400 --evaluation-periods 4 --alarm-actions arn:aws:automate:us-east-1:ec2:stop
```

To create an alarm to terminate an instance using the CLI

- At a command prompt, type:

```
% aws cloudwatch put-metric-alarm --alarm-name my-Alarm --alarm-description "Terminate the instance when it is idle for a day" --namespace "AWS/EC2" --dimensions Name=InstanceId,Value=i-abc123 --statistic Average --metric-name CPUUtilization --comparison-operator LessThanThreshold --threshold 1 --period 86400 --evaluation-periods 4 --alarm-actions arn:aws:automate:us-east-1:ec2:terminate
```

To create an alarm and to stop an instance using the API

The following example request shows how to create an alarm that stops an Amazon EC2 instance.

- Construct the following request:

```
http://monitoring.amazonaws.com/

?SignatureVersion=2
&Action=PutMetricAlarm
&Version=2009-05-15
&Namespace=AWS/EC2
&MetricName=CPUUtilization
```
To create an alarm and to terminate an instance using the API

The following example request shows how to create an alarm that terminates an Amazon EC2 instance.

- Construct the following request:

```
http://monitoring.amazonaws.com/
?SignatureVersion=2
&Action=PutMetricAlarm
&Version=2009-05-15
&Namespace=AWS/EC2
&MetricName=CPUUtilization
&Dimension.member.1.Name=instance-id
&Dimension.member.1.Value=i-abc123
&Period=86400
&Statistic=Average
&AlarmName=Terminate-EC2-Instance
```

Amazon CloudWatch Alarm Action Scenarios

You can use the Amazon Elastic Compute Cloud (Amazon EC2) console to create alarm actions that stop or terminate an Amazon EC2 instance when certain conditions are met. In the following screen capture of the console page where you set the alarm actions, we’ve numbered the settings. We’ve also numbered the settings in the scenarios that follow, to help you create the appropriate actions.

Scenario 1: Stop Idle Development and Test Instances

Create an alarm that stops an instance used for software development or testing when it has been idle for at least an hour.

<table>
<thead>
<tr>
<th>Seq</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop</td>
</tr>
<tr>
<td>2</td>
<td>Maximum</td>
</tr>
</tbody>
</table>
Scenario 2: Stop Idle Instances

Create an alarm that stops an instance and sends an email when the instance has been idle for 24 hours.

Scenario 3: Stop Web Servers with Unusually High Traffic

Create an alarm that sends email when an instance exceeds 10 GB of outbound network traffic per day.
Scenario 4: Stop Web Servers with Unusually High Traffic

Create an alarm that stops an instance and send a text message (SMS) if outbound traffic exceeds 1 GB per hour.

<table>
<thead>
<tr>
<th>Strg</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>

<td>1</td>
</tr>
</tbody>
</table>

Scenario 5: Stop an Instance Experiencing a Memory Leak

Create an alarm that stops an instance when memory utilization reaches or exceeds 90 percent, so that application logs can be retrieved for troubleshooting.

**Note**
The MemoryUtilization metric is a custom metric. In order to use the MemoryUtilization metric, you must install the Monitoring Scripts for Amazon EC2 Instances (p. 416).

<td>15 minutes</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
</tr>
</tbody>
</table>

Scenario 7: Terminate Instances When Batch Processing Jobs Are Complete

Create an alarm that terminates an instance that runs batch jobs when it is no longer sending results data.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Terminate</td>

</tr>
</tbody>
</table>

The previous scenarios can also be performed using the Amazon CloudWatch console. We’ve numbered the settings on the console to match the numbered settings in the Amazon EC2 console and the scenarios that we covered earlier, so you can make a comparison and create an alarm with the appropriate actions.
Monitoring Scripts for Amazon EC2 Instances

The Amazon CloudWatch Monitoring Scripts for Amazon Elastic Compute Cloud (Amazon EC2) Linux- and Windows-based instances demonstrate how to produce and consume Amazon CloudWatch custom metrics. The scripts for Linux are sample Perl scripts that comprise a fully functional example that reports memory, swap, and disk space utilization metrics for a Linux instance. The scripts for Windows are sample PowerShell scripts that comprise a fully functional example that reports memory, page file, and disk space utilization metrics for a Windows instance. You can download the CloudWatch Monitoring Scripts for Linux and for Windows from the Amazon Web Services (AWS) sample code library and install them on your Linux- or Windows-based instances.

Important

These scripts are examples only. They are provided "as is" and are not supported.

Note

Standard Amazon CloudWatch free tier quantities and usage charges for custom metrics apply to your use of these scripts. For more information, see the Amazon CloudWatch product page.

- Getting Started (p. 418)
- Using the Scripts (p. 418)
- Viewing Your Custom Metrics in the AWS Management Console (p. 422)

You can download the Amazon CloudWatch Monitoring Scripts for Linux from the AWS sample code library. The CloudWatchMonitoringScripts-v1.1.0.zip package contains these files:

- **CloudWatchClient.pm**—Shared Perl module that simplifies calling Amazon CloudWatch from other scripts.
- **mon-put-instance-data.pl**—Collects system metrics on an Amazon EC2 instance (memory, swap, disk space utilization) and sends them to Amazon CloudWatch.
- **mon-get-instance-stats.pl**—Queries Amazon CloudWatch and displays the most recent utilization statistics for the EC2 instance on which this script is executed.
- **—**File template for AWS credentials that stores your access key ID and secret access key.
- **LICENSE.txt**—Text file containing the Apache 2.0 license.
- **NOTICE.txt**—copyright notice.

These monitoring scripts are intended for use with Amazon EC2 instances running Linux operating systems. The scripts have been tested on the following Amazon Machine Images (AMIs) for both 32-bit and 64-bit versions:

- Amazon Linux 2011.09.02
- Red Hat Enterprise Linux 6.3
- Ubuntu Server 12.04
- SUSE Linux Enterprise Server 11

**Prerequisites**

You must perform additional steps on some versions of Linux.

**Amazon Linux AMI**

If you are running an Amazon Linux AMI, version 2014.03 or later, you’ll need to add some additional Perl modules in order for the monitoring scripts to work. Use the following procedure to configure your server.

- Log on to your Amazon Linux AMI instance and install the following packages:

  ```
sudo yum install perl-Switch perl-Sys-Syslog perl-LWP-Protocol-https
  ```

**Red Hat Enterprise Linux or SUSE Linux**

If you are running Red Hat Enterprise Linux or SUSE Linux Enterprise Server, use the following procedure to configure your server.
1. At a command prompt, type `cd /` to switch to the root directory.
2. Type `perl -MCPAN -e shell`, and then type `yes` at every prompt.
3. At the `cpan[1]>` prompt, type `install Bundle::LWP_837 LWP` to install the LWP bundle and update to LWP version 6.03. Type `yes` at every prompt.

**Ubuntu Server**

If you are running Ubuntu Server, use the following procedure to configure your server.

- Log on to your Ubuntu Server instance and install the following packages:

  ```
  sudo apt-get install unzip libwww-perl libcrypt-ssleay-perl
  ```

For information on how to connect to Amazon EC2 Linux instances, see Connecting to Instances in the Amazon Elastic Compute Cloud User Guide.

**Getting Started**

The following steps show you how to download, uncompress, and configure the CloudWatch Monitoring Scripts on an EC2 Linux instance.

**To download, install, and configure the script**

- Open a command prompt, move to a folder where you want to store the scripts and enter the following:

  ```
  wget http://ec2-downloads.s3.amazonaws.com/cloudwatch-samples/CloudWatchMonitoringScripts-v1.1.0.zip
  unzip CloudWatchMonitoringScripts-v1.1.0.zip
  rm CloudWatchMonitoringScripts-v1.1.0.zip
  cd aws-scripts-mon
  ```

**Using the Scripts**

**mon-put-instance-data.pl**

This script collects memory, swap, and disk space utilization data on the current system. It then makes a remote call to Amazon CloudWatch to report the collected data as custom metrics.

**Options**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--mem-util</code></td>
<td>Collects and sends the MemoryUtilization metrics in percentages. This option reports only memory allocated by applications and the operating system, and excludes memory in cache and buffers.</td>
</tr>
<tr>
<td><code>--mem-used</code></td>

### Examples

The following examples assume that you have already updated the `awscreds.conf` file with valid AWS credentials. If you are not using the `awscreds.conf` file, provide credentials using the `--aws-access-key-id` and `--aws-secret-key` arguments.

#### To perform a simple test run without posting data to CloudWatch

- Run the following command:

  ```bash
  ./mon-put-instance-data.pl --mem-util --verify --verbose
  ```

#### To collect all available memory metrics and send them to CloudWatch

- Run the following command:

  ```bash
  ./mon-put-instance-data.pl --mem-util --mem-used --mem-avail
  ```

#### To set a cron schedule for metrics reported to CloudWatch

1. Start editing the crontab using the following command:

   ```bash
   crontab -e
   ```

2. Add the following command to report memory and disk space utilization to CloudWatch every five minutes:

   ```bash
   */5 * * * * ~/aws-scripts-mon/mon-put-instance-data.pl --mem-util --disk-space-util --disk-path=/ --from-cron
   ```

If the script encounters an error, the script will write the error message in the system log.
mon-get-instance-stats.pl

This script queries CloudWatch for statistics on memory, swap, and disk space metrics within the time interval provided using the number of most recent hours. This data is provided for the Amazon EC2 instance on which this script is executed.

Examples

To get utilization statistics for the last 12 hours

- Run the following command:

```
mon-get-instance-stats.pl --recent-hours=12
```

The returned response will be similar to the following example output:

```
Instance metric statistics for the last 12 hours.

CPU Utilization
  Average: 1.06%, Minimum: 0.00%, Maximum: 15.22%

Memory Utilization
  Average: 6.84%, Minimum: 6.82%, Maximum: 6.89%

Swap Utilization
  Average: N/A, Minimum: N/A, Maximum: N/A
```
Disk Space Utilization on /dev/xvdal mounted as /  
   Average: 9.69%, Minimum: 9.69%, Maximum: 9.69%

Viewing Your Custom Metrics in the AWS Management Console

If you successfully call the mon-put-instance-data.pl script, you can use the AWS Management Console to view your posted custom metrics in the Amazon CloudWatch console.

To view custom metrics

1. Execute mon-put-instance-data.pl, as described earlier.
2. Sign in to the AWS Management Console and open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
3. Click View Metrics.
4. In the Viewing drop-down list, your custom metrics posted by the script display with the prefix System/Linux.

Amazon CloudWatch Monitoring Scripts for Windows

The Amazon CloudWatch Monitoring Scripts for Windows are sample PowerShell scripts that demonstrate how to produce and consume Amazon CloudWatch custom metrics. The scripts comprise a fully functional example that reports memory, page file, and disk space utilization metrics for an Amazon Elastic Compute Cloud (Amazon EC2) Windows instance.

Topics

• Getting Started (p. 423)
• Using the Scripts (p. 423)

You can download Amazon CloudWatch Monitoring Scripts for Microsoft Windows Server from the Amazon Web Services (AWS) sample code library. The AmazonCloudWatchMonitoringWindows.zip package contains these files:

• mon-put-metrics-mem.ps1 — Collects system metrics on an Amazon EC2 Windows instance (memory, page file utilization) and sends them to Amazon CloudWatch.
• mon-put-metrics-disk.ps1 — Collects system metrics on an Amazon EC2 instance (disk space utilization) and sends them to Amazon CloudWatch.
• mon-put-metrics-perfmon.ps1 — Collects PerfMon counters on an Amazon EC2 instance and sends them to Amazon CloudWatch.
• mon-get-instance-stats.ps1 — Queries Amazon CloudWatch and displays the most recent utilization statistics for the EC2 instance on which this script is executed.
• awscreds.conf — File template for AWS credentials that stores your access key ID and secret access key.
• LICENSE.txt — Text file containing the Apache 2.0 license.
• NOTICE.txt — Copyright notice.
These monitoring scripts are intended for use with Amazon EC2 instances running Microsoft Windows Server. The scripts have been tested on the following Amazon Machine Images (AMIs) for both 32-bit and 64-bit versions:

- Windows Server 2003 R2
- Windows Server 2008
- Windows Server 2008 R2

**Getting Started**

The following steps demonstrate how to download, uncompress, and configure the Amazon CloudWatch Monitoring Scripts on an Amazon EC2 Windows instance.

**To download, install, and configure the script**

1. Connect to your Amazon EC2 Windows instance. For information about how to connect to Amazon EC2 Windows instances, see Connecting to Windows Instances in the Amazon Elastic Compute Cloud User Guide.
2. Download and install the AWS SDK for .NET onto the EC2 instance that you want to monitor.
3. Download the .zip file containing the Amazon CloudWatch Monitoring Scripts for Microsoft Windows Server onto the EC2 instance and unzip it in a location of your preference.
4. Update the awscreds.conf file that you downloaded earlier. The content of this file should use the following format:

```
AWSAccessKeyId=YourAccessKeyID
AWSSecretKey=YourSecretAccessKey
```

**Note**

This step is optional if you have already created a file for credentials. You can use an existing file by specifying its location on the command line when you call the scripts. Alternatively, you can set the environment variable AWS_CREDENTIAL_FILE to point to the file with your AWS credentials. For instructions on how to access your credentials, use the following procedure.

As a best practice, do not use the root credentials. Instead, you should create an Identity and Access Management (IAM) user with a policy that restricts the user to only Amazon CloudWatch operations. For more information, see Controlling User Access to Your AWS Account.

**Using the Scripts**

### mon-put-metrics-mem.ps1

This script collects memory and pagefile utilization data on the current system. It then makes a remote call to Amazon CloudWatch to report the collected data as custom metrics.

Examples

The following examples assume that you have already updated the `awscreds.conf` file with valid AWS credentials. If you are not using the `awscreds.conf` file, provide credentials using the `-aws_access_id` and `-aws_secret_key` arguments.

To collect all available memory metrics using an inline access ID and secret key and send the data to CloudWatch

- Run the following command:

  ```powershell
  .\mon-put-metrics-mem.ps1 -aws_access_id ThisIsMyAccessKey -aws_secret_key ThisIsMySecretKey -mem_util -mem_avail -page_avail -page_used -page_util -memory_units Megabytes
  ```

To collect all available memory metrics using a credential file and send the data to CloudWatch

- Run the following command:

  ```powershell
  .\mon-put-metrics-mem.ps1 -aws_credential_file C:\awscreds.conf -mem_util -mem_used -mem_avail -page_avail -page_used -page_util -memory_units Megabytes
  ```

To collect all available memory metrics using credentials stored in environment variables and send the data to CloudWatch

- Run the following command:

  ```powershell
  .\mon-put-metrics-mem.ps1 -mem_util -mem_used -mem_avail -page_avail -page_used -page_util -memory_units Megabytes
  ```

`mon-put-metrics-disk.ps1`

Amazon Elastic Compute Cloud User Guide
Amazon CloudWatch Monitoring Scripts for Windows

Name

Description

-verbose

Displays detailed information about what the script is doing.

Get-help
Displays usage information.
mon-put-metrics-disk.ps1
-version

Displays the version number of the script.

-logfile

Logfile is used to log error message. Use this along with
–from_scheduler option. If no value is specified for logfile then a
default file is created with the same as the script with .log extension.

Examples
To collect preset PerfMon counters in script using an inline access ID and secret key and
send the data to Amazon CloudWatch
•

Run the following command:
.\mon-put-metrics-perfmon.ps1 -aws_access_id ThisIsMyAccessKey -aws_secret_key
ThisIsMySecretKey -pages_input -processor_queue

To collect preset PerfMon counters in script using a credential file and send the data to
Amazon CloudWatch
•

Run the following command:
.\mon-put-metrics-perfmon.ps1
pages_input -processor_queue

-aws_credential_file C:\awscreds.conf -

To collect preset PerfMon counters in script using credentials stored in an environment
variable and send the data to Amazon CloudWatch
•

Run the following command:
.\mon-put-metrics-perfmon.ps1 -pages_input -processor_queue

To add more counters to be pushed to Amazon CloudWatch
1.

Open the script in a text editor such as Notepad, and then on line 72, locate the following commented
section:
### Add More counters here.
#$Counters.Add('\Memory\Cache Bytes','Bytes')
#$Counters.Add('\\localhost\physicaldisk(0 c:)\% disk time','Percent')

API Version 2014-02-01
428


Note
The first parameter (e.g., $Counters.Add) is the PerfMon counter. The second parameter (e.g., ('Memory/Cache Bytes', 'Bytes')) is the unit of data that counter provides.

2. Edit the script and add your own PerfMon counters to the script as shown above. After you have added custom PerfMon counters to the script, you can run the script without any parameters other than credential information.

Note
You can only add PerfMon counters to the script on your computer. You can use the Get-Counter command to test PerfMon counters. For more information, see Get-Counter on the Microsoft TechNet website.

mon-get-instance-stats.ps1

This script queries Amazon CloudWatch for statistics on memory, page file, and disk space metrics within the time interval provided using the number of most recent hours. This data is provided for the Amazon EC2 instance on which this script is executed.

Options

Set Up Task Scheduler to Send Metrics Reports to Amazon CloudWatch

You can use Windows Task Scheduler to send metrics reports periodically to Amazon CloudWatch.
To set up task scheduler to send metrics reports to Amazon CloudWatch

1. On your Windows Server instance, click **Start**, click **Administrative Tools**, and then click **Task Scheduler**.
2. On the **Action** menu, click **Create Task**.
3. In the **Create Task** dialog box, on the **General** tab, in the **Name** box, type a name for the task, and then select **Run whether user is logged on or not**.
4. On the **Triggers** tab, click **New**.
5. In the **New Trigger** dialog box, under **Settings**, select **One time**.
6. Under **Advanced settings**, select **Repeat task every** and select **5 minutes** from the drop-down menu.
7. In the **for a duration of** drop-down menu, select **Indefinitely**, and then click **OK**.
   **Note**
   These settings create a trigger that will launch the script every 5 minutes indefinitely. To modify this task to run for set number of days using the **Expire** check box.
8. On the **Actions** tab, click **New**.
9. In the **Action** drop-down menu, select **Start a program**.
10. Under **Settings**, in the **Program/script** box, type **Powershell.exe**.
11. In the **Add arguments (optional)** box, type ```-command "C:\scripts\mon-put-metrics-disk.ps1 -disk_drive C:,d -disk_space_util -disk_space_units gigabytes -from_scheduler -logfile C:\mylogfile.log"``` , and then click **OK**.
12. On the **Create Task** dialog box, click **OK**.

   If you selected a user account to run this task, Task Scheduler will prompt you for user credentials. Enter the user name and password for the account that will run the task, and then click **OK**.

   **Note**
   If the PerfMon counters you are using don’t require administrator privileges, you can run this task using a system account instead of an administrator account. In the **Create Task** dialog box, on the **General** tab, click **Change User or Group**, and then select a system account.
Network and Security

This section describes key network and security features related to Amazon EC2.

Topics

- Amazon EC2 Key Pairs (p. 433)
- Amazon EC2 Security Groups (p. 440)
- Controlling Access to Amazon EC2 Resources (p. 448)
- Amazon EC2 and Amazon Virtual Private Cloud (VPC) (p. 485)
- Amazon EC2 Instance IP Addressing (p. 489)
- Elastic IP Addresses (EIP) (p. 498)
- Elastic Network Interfaces (ENI) (p. 503)
- Enabling Enhanced Networking on Linux Instances in a VPC (p. 516)

If you access Amazon EC2 using the command line tools or an API, you'll need your access key ID and secret access key. For more information, see How Do I Get Security Credentials?

You can launch an instance into one of two platforms: EC2-Classic or EC2-VPC. An instance that's launched into EC2-Classic or a default VPC is automatically assigned a public IP address. An instance that's launched into a nondefault VPC can be assigned a public IP address on launch. For more information about EC2-Classic and EC2-VPC, see Supported Platforms.

Instances can fail or terminate for reasons outside of your control. If an instance fails and you launch a replacement instance, the replacement has a different public IP address than the original. However, if your application needs a static IP address, you can use an Elastic IP address.

You can use security groups to control who can access your instances. These are analogous to an inbound network firewall that enables you to specify the protocols, ports, and source IP ranges that are allowed to reach your instances. You can create multiple security groups and assign different rules to each group. You can then assign each instance to one or more security groups, and we use the rules to determine which traffic is allowed to reach the instance. You can configure a security group so that only specific IP addresses or specific security groups have access to the instance.
Amazon EC2 Key Pairs

Amazon EC2 uses public–key cryptography to encrypt and decrypt login information. Public–key cryptography uses a public key to encrypt a piece of data, such as a password, then the recipient uses the private key to decrypt the data. The public and private keys are known as a key pair.

To log in to your instance, you must create a key pair, specify the name of the key pair when you launch the instance, and provide the private key when you connect to the instance. Linux/Unix instances have no password, and you use a key pair to log in using SSH. With Windows instances, you use a key pair to obtain the administrator password and then log in using RDP.

Creating a Key Pair

You can use Amazon EC2 to create your key pair. For more information, see Creating Your Key Pair Using Amazon EC2 (p. 433).

Alternatively, you could use a third-party tool and then import the public key to Amazon EC2. For more information, see Importing Your Own Key Pair to Amazon EC2 (p. 435).

Each key pair requires a name. Be sure to choose a name that is easy to remember. Amazon EC2 associates the public key with the name that you specify as the key name.

Amazon EC2 stores the public key only, and you store the private key. Anyone who possesses your private key can decrypt your login information, so it’s important that you store your private keys in a secure place.

The keys that Amazon EC2 uses are 1024-bit SSH-2 RSA keys. You can have up to five thousand key pairs per region.

Launching and Connecting to Your Instance

When you launch an instance, you should specify the name of the key pair you plan to use to connect to the instance. If you don’t specify the name of an existing key pair when you launch an instance, you won’t be able to connect to the instance. When you connect to the instance, you must specify the private key that corresponds to the key pair you specified when you launched the instance. Amazon EC2 doesn’t keep a copy of your private key; therefore, if you lose your private key, there is no way to recover it. If you lose the private key for an instance store-backed instance, you can’t access the instance; you should terminate the instance and launch another instance using a new key pair. If you lose the private key for an EBS-backed instance, you can regain access to your instance. For more information, see Connecting to Your Instance if You Lose Your Private Key (p. 438).

Creating Your Key Pair Using Amazon EC2

You can create a key pair using the Amazon EC2 console or the command line.

To create your key pair using the console

1. Open the Amazon EC2 console.
2. From the navigation bar, select a region for the key pair. You can select any region that's available to you, regardless of your location. This choice is important because some Amazon EC2 resources can be shared between regions, but key pairs can't. For example, if you create a key pair in the US West (Oregon) Region, you can't see or use the key pair in another region.

3. Click **Key Pairs** in the navigation pane.

4. Click **Create Key Pair**.

5. Enter a name for the new key pair in the **Key pair name** field of the **Create Key Pair** dialog box, and then click **Create**.

6. The private key file is automatically downloaded by your browser. The base file name is the name you specified as the name of your key pair, and the file name extension is `.pem`. Save the private key file in a safe place.

   **Important**

   This is the only chance for you to save the private key file. You'll need to provide the name of your key pair when you launch an instance and the corresponding private key each time you connect to the instance.

7. If you will use an SSH client on a Mac or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

   ```
   $ chmod 400 my-key-pair.pem
   ```

To create your key pair using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `create-key-pair` (AWS CLI)
- `ec2-create-keypair` (Amazon EC2 CLI)
- `New-EC2KeyPair` (AWS Tools for Windows PowerShell)
Importing Your Own Key Pair to Amazon EC2

If you used Amazon EC2 to create your key pair, as described in the previous section, you are ready to launch an instance. Otherwise, instead of using Amazon EC2 to create your key pair, you can create an RSA key pair using a third-party tool and then import the public key to Amazon EC2. For example, you can use `ssh-keygen` (a tool provided with the standard OpenSSH installation) to create a key pair. Alternatively, Java, Ruby, Python, and many other programming languages provide standard libraries that you can use to create an RSA key pair.

Amazon EC2 accepts the following formats:

- OpenSSH public key format (the format in `~/.ssh/authorized_keys`)
- Base64 encoded DER format
- SSH public key file format as specified in RFC4716

Amazon EC2 does not accept DSA keys. Make sure your key generator is set up to create RSA keys.

Supported lengths: 1024, 2048, and 4096.

**To create a key pair using a third-party tool**

1. Generate a key pair with a third-party tool of your choice.
2. Save the public key to a local file. For example, `C:\keys\my-key-pair.pub`. The file name extension for this file is not important.
3. Save the private key to a different local file that has the `.pem` extension. For example, `C:\keys\my-key-pair.pem`. Save the private key file in a safe place. You'll need to provide the name of your key pair when you launch an instance and the corresponding private key each time you connect to the instance.

Use the following steps to import your key pair using the Amazon EC2 console. (If you prefer, you can use the `ec2-import-keypair` command or the `ImportKeyPair` action to import the public key.)

**To import the public key**

1. Open the Amazon EC2 console.
2. From the navigation bar, select the region for the key pair. This choice is important because key pair resources cannot be shared between regions. For example, if you import a key pair into the US West (Oregon) Region, you won't be able to see or use the key pair in another region.
3. Click Key Pairs in the navigation pane.
4. Click Import Key Pair.
5. In the Import Key Pair dialog box, click Browse, and select the public key file that you saved previously. Enter a name for the key pair in the Key pair name field, and click Import.

After the public key file is imported, you can verify that the key pair was imported successfully using the Amazon EC2 console as follows. (If you prefer, you can use the ec2-describe-keypairs command or the DescribeKeyPairs action to list your key pairs.)

To verify that your key pair was imported
1. From the navigation bar, select the region in which you created the key pair.
2. Click Key Pairs in the navigation pane.
3. Verify that the key pair that you imported is in the displayed list of key pairs.

Retrieving the Public Key for Your Key Pair

On a Linux/Unix instance, the public key content is placed in an entry within ~/.ssh/authorized_keys. This is done at boot time and enables you to securely access your instance without passwords. You can open this file in an editor to view the public key for your key pair. The following is an example entry for the key pair named my-key-pair. It consists of the public key followed by the name of the key pair. For example:

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6Vhz2ItxCih+PnSUaw+WNQN/m2phTk/a/gU8jEzoOWbkM4yxxyb/wB96xb1FveSFJuOq/d6RJhJ0I0ibXr1sJnBItntcikJ7FbtxJMXLvwwJryDUUlBMTjytwB+QhYXUMOzce5Pjz5/i8SeJtjnV3iAoG/cQk+0FzZqeeJAHCQ+Wg+5r/7+KyU/A0f88q+Vb/I8GZo42AbXZy/j+z673JkAhp8Xly5okp5b2VJyq0q9B9JP/yrU+5T7Q3Xw+Ft2hGPXWLMJ+fJH9jleJcBl8N1aC5QnA9a2onOm76Zv5wOvQ4k2j/B9J56nQd/9+fpcXJj57N2u308f3wJ1GvnWJZd6a7qM7sMGiH/Rb6G7LsQ9vZr27A3WJmS8V6i6eTMA== my-key-pair
```

On Linux/Unix, you can use ssh-keygen to get the public key for your key pair. Run the following command on a computer to which you've downloaded your private key:
When prompted by `ssh-keygen`, specify the path to your .pem file. The command returns the public key. For example:

```plaintext
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS7O6V
hz2ItxCwh+PnDSUaw+WNQn/m2hTk/a/gUj3EzoOWbkM4xyyb/wB96xbIFveSFJuOp/d6RJhJOIiBXr
lSnBtntckiJ7FbtxJMXLvvwJryDU1iBMTrjTwb+QyXUMOzce5Pjz5/i8SeJtjnV3iAoG/cQk+OFZ
qaeJAAHco+CY/5WrUbkrHmFJR6HcXkvkJdWPkYQS3xqC0+FmU2ofz221C8t5IMucxXPkX4rWi+z7wB3Rb
BQoQzd8v7yeb7Oz1PnWOyN0QFU0XA246RA8QFYiCNYwI3f05p6RLxEXAMPLE
```

On Windows, you can use PuTTYgen to get the public key for your key pair. Start PuTTYgen, click **Load**, and select the .ppk or .pem file. PuTTYgen displays the public key.

The public key that you specified when you launched an instance is also available to you through its instance metadata. To view the public key that you specified when launching the instance, use the following command from your instance:

```plaintext
```

Note that if you change the key pair that you use to connect to the instance, as shown in the next section on this page, we don't update the instance metadata to show the new public key; you'll continue to see the public key for the key pair you specified when you launched the instance in the instance metadata. For more information about instance metadata, see Retrieving Instance Metadata (p. 269).

### Deleting Your Key Pair

When you delete a key pair, you are only deleting Amazon EC2's copy of the public key. Deleting a key pair doesn't affect the private key on your computer or the public key on any instances already launched using that key pair. You can't launch a new instance using a deleted key pair, but you can continue to connect to any instances that you launched using a deleted key pair, as long as you still have the private key (.pem) file.

You can delete a key pair using the Amazon EC2 console or the command line.

#### To delete your key pair using the console

1. Open the Amazon EC2 console.
2. Click **Key Pairs** in the navigation pane.
3. Select the key pair and click **Delete**.
4. When prompted, click **Yes**.

#### To delete your key pair using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `delete-key-pair` (AWS CLI)
- `ec2-delete-keypair` (Amazon EC2 CLI)
Connecting to Your Instance if You Lose Your Private Key

If you lose the private key for an EBS-backed instance, you can regain access to your instance. You must stop the instance, detach its root volume and attach it to another instance as a data volume, modify the authorized_keys file, move the volume back to the original instance, and restart the instance. This procedure isn’t supported for instance store-backed instances or instances whose root volume has an AWS Marketplace product code. For more information about launching, connecting to, and stopping instances, see Instance Lifecycle (p. 297).

To determine the root device type of your instance, open the Amazon EC2 console, click Instances, select the instance, and check the value of Root device type in the details pane. The value is either ebs or instance store. If the root device is an instance store volume, you must have the private key in order to connect to the instance. You can also check the value of Product codes in the details pane to determine whether you're using an AWS Marketplace product code.

Prerequisites

Create a new key pair using either the Amazon EC2 console or a third-party tool.

To connect to an EBS-backed instance with a different key pair

1. From the Amazon EC2 console, click Instances in the navigation pane, and select the instance that you'd like to connect to. (We'll refer to this as the original instance.)
2. Save the following information that you'll see to complete this procedure.
   • Write down the instance ID (i-xxxxxxxx), AMI ID (ami-xxxxxxxx), and Availability Zone of the original instance.
   • Click the entry for sda1 (the root volume) under Block devices in the details pane and write down the volume ID (vol-xxxxxxxx).
   • [EC2-Classic] If the original instance has an associated Elastic IP address, write down the Elastic IP address shown under Elastic IP in the details pane.
3. Click Actions, and then click Stop. If Stop is disabled, either the instance is already stopped or its root device is an instance store volume.
4. Launch a temporary instance using the console with the following options:
   • On the Choose an AMI page, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see Creating an Amazon EBS-Backed Linux AMI (p. 69).
   • On the Choose and Instance Type page, select a t1.micro instance.
   • On the Configure Instance Details page, specify the same Availability Zone as the instance you'd like to connect to. If you're launching an instance in a VPC, select a subnet in this Availability Zone.
   • On the Tag Instance page, add the tag Name=Temporary to the instance to indicate that this is a temporary instance.
   • On the Review page, click Launch. Specify the new key pair that you created, and then click Launch Instances.
5. In the navigation pane, click **Volumes** and select the root device volume for the original instance (you wrote down its volume ID in a previous step). Click **Actions**, and then click **Detach Volume**. Wait for the state of the volume to become **available**. (You might need to click the **Refresh** icon.)

6. With the volume still selected, click **Actions**, and then click **Attach Volume**. Select the instance ID of the temporary instance, write down the device name specified under **Device** (for example, /dev/sdf), and then click **Yes, Attach**.

7. Connect to the temporary instance.

8. From the temporary instance, mount the volume that you attached to the instance so that you can access its file system. For example, if the device name is /dev/sdf, use the following commands to mount the volume as /mnt/tempvol:

   ```bash
   $ sudo mkdir /mnt/tempvol
   $ sudo mount /dev/sdf /mnt/tempvol
   ```

9. From the temporary instance, use the following command to update **authorized_keys** on /dev/sdf with the new public key from the **authorized_keys** for the temporary instance:

   ```bash
   $ cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   If this copy succeeded, you can go to the next step.

   (Optional) Otherwise, if you don't have permission to edit files in /mnt/tempvol, you'll need to update the file using **sudo** and then check the permissions on the file to verify that you'll be able to log into the original instance. Use the following command to check the permissions on the file:

   ```bash
   $ sudo ls -l /mnt/home/ec2-user/.ssh
   total 4
   -rw------- 1 222 500 398 Sep 13 22:54 authorized_keys
   ```

   In this example output, **222** is the user ID and **500** is the group ID. Next, use **sudo** to re-run the copy command that failed:

   ```bash
   $ sudo cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   Run the following command again to determine whether the permissions changed:

   ```bash
   $ sudo ls -l /mnt/home/ec2-user/.ssh
   ```

   If the user ID and group ID have changed, use the following command to restore them:

   ```bash
   $ sudo chown 222:500 /mnt/home/ec2-user/.ssh/authorized_keys
   ```

10. From the temporary instance, unmount the volume that you attached so that you can reattach it to the original instance. For example, use the following command to unmount /dev/sdf:

    ```bash
    $ sudo umount -d /dev/sdf
    ```

11. From the Amazon EC2 console, select the volume with the volume ID that you wrote down, click **Actions**, and then click **Detach Volume**. Wait for the state of the volume to become **available**. (You might need to click the **Refresh** icon.)
12. With the volume still selected, click Actions, and then click Attach Volume. Select the instance ID of the original instance, specify the device name /dev/sda1, and then click Yes, Attach.

**Warning**
If you don’t specify sda1 as the device name, you’ll be unable to start the original instance. This is because Amazon EC2 expects the root device volume at sda1.

13. Select the original instance, click Actions, and then click Start. After the instance enters the running state, you can connect to it using the private key file for your new key pair.

14. [EC2-Classic] If the original instance had an associated Elastic IP address before you stopped it, you must re-associate it with the instance as follows:
   a. In the navigation pane, click Elastic IPs.
   b. Select the Elastic IP address that you wrote down at the beginning of this procedure.
   c. Click Associate Address.
   d. Select the ID of the original instance, and then click Associate.

15. (Optional) You can terminate the temporary instance if you have no further use for it. Select the temporary instance, click Actions, and then click Terminate.

### Amazon EC2 Security Groups

A *security group* acts as a virtual firewall that controls the traffic for one or more instances. When you launch an instance, you associate one or more security groups with the instance. You add rules to each security group that allow traffic to or from its associated instances. You can modify the rules for a security group at any time; the new rules are automatically applied to all instances that are associated with the security group. When we decide whether to allow traffic to reach an instance, we evaluate all the rules from all the security groups that are associated with the instance.

This topic provides information about security groups and security group rules.

**Topics**
- Security Groups for EC2-Classic (p. 440)
- Security Groups for EC2-VPC (p. 441)
- Security Group Rules (p. 441)
- Default Security Groups (p. 442)
- Custom Security Groups (p. 442)

- Adding Rules to a Security Group (p. 445)
- Deleting Rules from a Security Group (p. 446)
- Deleting a Security Group (p. 446)
- API and Command Overview (p. 446)

If you have requirements that aren’t met by security groups, you can maintain your own firewall on any of your instances in addition to using security groups.

### Security Groups for EC2-Classic

If you’re using EC2-Classic, you must use security groups created specifically for EC2-Classic. When you launch an instance in EC2-Classic, you must specify a security group in the same region as the
instance. You can't specify a security group that you created for a VPC when you launch an instance in EC2-Classic.

After you launch an instance in EC2-Classic, you can't change its security groups. However, you can add rules to or remove rules from a security group, and those changes are automatically applied to all instances that are associated with the security group.

**Note**
In EC2-Classic, you can associate an instance with up to 500 security groups and add up to 100 rules to a security group.

### Security Groups for EC2-VPC

If you're using EC2-VPC, you must use security groups created specifically for your VPC. When you launch an instance in a VPC, you must specify a security group for that VPC. You can't specify a security group that you created for EC2-Classic when you launch an instance in a VPC.

After you launch an instance in a VPC, you can change its security groups. You can also change the rules of a security group, and those changes are automatically applied to all instances that are associated with the security group.

**Note**
In EC2-VPC, you can associate a network interface with up to 5 security groups and add up to 50 rules to a security group.

When you specify a security group for a nondefault VPC to the CLI or the API actions, you must use the security group ID and not the security group name to identify the security group.

Security groups for EC2-VPC have additional capabilities that aren't supported by security groups for EC2-Classic. For more information about security groups for EC2-VPC, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

### Security Group Rules

The rules of a security group control the inbound traffic that's allowed to reach the instances that are associated with the security group and the outbound traffic that's allowed to leave them. By default, security groups allow all outbound traffic.

You can add and remove rules at any time. Your changes are automatically applied to the instances associated with the security group after a short period. You can either edit an existing rule in a security group, or delete it and add a new rule. You can copy the rules from an existing security group to a new security group. You can't change the outbound rules for EC2-Classic. Security group rules are always permissive; you can't create rules that deny access.

For each rule, you specify the following:

- The protocol to allow (such as TCP, UDP, or ICMP).
- TCP and UDP, or a custom protocol: The range of ports to allow
- ICMP: The ICMP type and code
- One or the following options for the source (inbound rules) or destination (outbound rules):
  - An individual IP address, in CIDR notation. Be sure to use the /32 prefix after the IP address; if you use the /0 prefix after the IP address, this opens the port to everyone. For example, specify the IP address 203.0.113.1 as 203.0.113.1/32.
  - An IP address range, in CIDR notation (for example, 203.0.113.0/24).
  - The name (EC2-Classic) or ID (EC2-Classic or EC2-VPC) of a security group. This allows instances associated with the specified security group to access instances associated with this security group.
(Note that this does not add rules from the source security group to this security group.) You can specify one of the following security groups:

- The current security group.
- EC2-Classic: A different security group for EC2-Classic in the same region
- EC2-VPC: A different security group for the same VPC
- EC2-Classic: A security group for another AWS account in the same region (add the AWS account ID as a prefix; for example, 111122223333/sg-edcd9784)

When you specify a security group as the source or destination for a rule, the rule affects all instances associated with the security group. For example, incoming traffic is allowed based on the private IP addresses of the instances that are associated with the source security group.

If there is more than one rule for a specific port, we apply the most permissive rule. For example, if you have a rule that allows access to TCP port 22 (SSH) from IP address 203.0.113.1 and another rule that allows access to TCP port 22 from everyone, everyone has access to TCP port 22.

When you associate multiple security groups with an instance, the rules from each security group are effectively aggregated to create one set of rules. We use this set of rules to determine whether to allow access.

Caution
Because you can assign multiple security groups to an instance, an instance can have hundreds of rules that apply. This might cause problems when you access the instance. Therefore, we recommend that you condense your rules as much as possible.

For more information about IP addresses, see Amazon EC2 Instance IP Addressing (p. 489).

Default Security Groups

Your AWS account automatically has a default security group per region for EC2-Classic. When you create a VPC, we automatically create a default security group for the VPC. If you don't specify a different security group when you launch an instance, the instance is automatically associated with the appropriate default security group.

A default security group is named default, and it has an ID assigned by AWS. The following are the initial settings for each default security group:

- Allow inbound traffic only from other instances associated with the default security group
- Allow all outbound traffic from the instance

The default security group specifies itself as a source security group in its inbound rules. This is what allows instances associated with the default security group to communicate with other instances associated with the default security group.

You can change the rules for a default security group. For example, you can add an inbound rule to allow SSH or Remote Desktop connections so that specific hosts can manage the instance.

You can't delete a default security group.

Custom Security Groups

If you don't want all your instances to use the default security group, you can create your own security groups and specify them when you launch your instances. You can create multiple security groups to reflect the different roles that your instances play; for example, a web server or a database server. For
instructions that help you create security groups for web servers and database servers, see Recommended Security Groups in the Amazon Virtual Private Cloud User Guide.

Note
In EC2-Classic, you can create up to 500 security groups in each region for each account. In EC2-VPC, you can create up to 100 security groups per VPC. The security groups for EC2-Classic do not count against the security group limit for EC2-VPC.

When you create a security group, you must provide it with a name and a description. Security group names and descriptions can be up to 255 characters in length, and are limited to the following characters:

- EC2-Classic: ASCII characters
- EC2-VPC: a-z, A-Z, 0-9, spaces, and _:-/()#,@[]+=&;{}!$*

AWS assigns each security group a unique ID in the form sg-xxxxxxxx. The following are the initial settings for a security group that you create:

- Allow no inbound traffic
- Allow all outbound traffic

After you've created a security group, you can change its inbound rules to reflect the type of inbound traffic that you want to reach the associated instances. In EC2-VPC, you can also change its outbound rules.

To allow instances that have the same security group to communicate, you must explicitly add rules for this. The following table describes the rules that you must add to your security group to enable instances in EC2-Classic to communicate.

Creating a Security Group

To create a new security group

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Click Create Security Group.
4. Specify a name and description for the security group. For VPC, select No VPC to create a security group for EC2-Classic, or select a VPC ID to create a security group for that VPC.
5. You can start adding rules, or you can click Create to create the security group now (you can always add rules later). For more information about adding rules, see Adding Rules to a Security Group (p. 445).

To copy a security group

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Select the security group you want to copy, click Actions, and then select Copy to new.
4. The Create Security Group dialog opens, and is populated with the rules from the existing security group. Specify a name and description for your new security group. In the VPC list, select No VPC to create a security group for EC2-Classic, or select a VPC ID to create a security group for that VPC. When you are done, click Create.

You can assign a security group to an instance when you launch the instance. When you add or remove rules, those changes are automatically applied to all instances to which you've assigned the security group.

After you launch an instance in EC2-Classic, you can't change its security groups. After you launch an instance in a VPC, you can change its security groups. For more information, see Changing an Instance’s Security Groups in the Amazon Virtual Private Cloud User Guide.

Describing Your Security Groups

To describe your security groups for EC2-Classic

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Select EC2 security groups from the filter list.
4. Select a security group. We display general information in the Description tab and inbound rules on the Inbound tab.

To describe your security groups for EC2-VPC

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Select VPC security groups from the filter list.
4. Select a security group. We display general information in the Description tab, inbound rules on the Inbound tab, and outbound rules on the Outbound tab.
Adding Rules to a Security Group

When you add a rule to a security group, the new rule is automatically applied to any instances associated with the security group.

To add rules to a security group

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Select the security group.
4. You can allow web servers to receive all inbound HTTP and HTTPS traffic. On the Inbound tab, click Edit. In the dialog, click Add Rule. Select HTTP from the Type list, and leave the source as Anywhere (0.0.0.0/0). Add a similar rule for the HTTPS protocol.

5. To connect to a Linux instance, you need to allow SSH traffic. Click Add Rule, and then select SSH from the Type list.

In the Source field, specify the public IP address of your computer, in CIDR notation. For example, if your IP address is 203.0.113.25, specify 203.0.113.25/32 to list this single IP address in CIDR notation. If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24. You can select My IP to from the Source list to let us automatically populate the field with your computer's IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Caution
If you use 0.0.0.0/0, you enable all IP addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you'll authorize only a specific IP address or range of addresses to access your instance.

6. You can allow communication between all instances associated with this security group, or between instances associated with another security group and instances associated with this security group. Click Add Rule, select All ICMP, then start typing the ID of the security group in Source; this provides you with a list of security groups. Select the security group from the list. Repeat the steps for the TCP and UDP protocols. Click Save when you are done.
7. If you are creating a security group for a VPC, you can also specify outbound rules. For an example, see Adding and Removing Rules in the *Amazon Virtual Private Cloud User Guide*.

### Deleting Rules from a Security Group

When you delete a rule from a security group, the change is automatically applied to any instances associated with the security group.

**To delete a security group rule**

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Select a security group.
4. Click Edit, and then click the Delete icon next to each rule that you need to delete.
5. Click Save.

### Deleting a Security Group

You can't delete a security group that associated with an instance. You can't delete the default security group.

**To delete a security group**

1. Open the Amazon EC2 console.
2. In the navigation pane, click Security Groups.
3. Select a security group and click Delete.
4. Click Yes, Delete.

### API and Command Overview

You can perform the tasks described on this page using the command line or an API. For more information about the command line interfaces and a list of available APIs, see Accessing Amazon EC2 (p. 3).

**Create a security group**

- `create-security-group` (AWS CLI)
• **ec2-create-group** (Amazon EC2 CLI)
• **New-EC2SecurityGroup** (AWS Tools for Windows PowerShell)

**Add one or more ingress rules to a security group**

• **authorize-security-group-ingress** (AWS CLI)
• **ec2-authorize** (Amazon EC2 CLI)
• **Grant-EC2SecurityGroupIngress** (AWS Tools for Windows PowerShell)

[EC2-VPC] **Add one or more egress rules to a security group**

• **authorize-security-group-egress** (AWS CLI)
• **ec2-authorize** (Amazon EC2 CLI)
• **Grant-EC2SecurityGroupIngress** (AWS Tools for Windows PowerShell)

**Describe one or more security groups**

• **describe-security-groups** (AWS CLI)
• **ec2-describe-group** (Amazon EC2 CLI)
• **Get-EC2SecurityGroup** (AWS Tools for Windows PowerShell)

[EC2-VPC] **Modify the security groups for an instance**

• **modify-instance-attribute** (AWS CLI)
• **ec2-modify-instance-attribute** (Amazon EC2 CLI)
• **Edit-EC2InstanceAttribute** (AWS Tools for Windows PowerShell)

**Remove one or more ingress rules from a security group**

• **revoke-security-group-ingress** (AWS CLI)
• **ec2-revoke** (Amazon EC2 CLI)
• **Revoke-EC2SecurityGroupIngress** (AWS Tools for Windows PowerShell)

[EC2-VPC] **Remove one or more egress rules from a security group**

• **revoke-security-group-egress** (AWS CLI)
• **ec2-revoke** (Amazon EC2 CLI)
• **Revoke-EC2SecurityGroupEgress** (AWS Tools for Windows PowerShell)

**Delete a security group**

• **delete-security-group** (AWS CLI)
• **ec2-delete-group** (Amazon EC2 CLI)
• **Remove-EC2SecurityGroup** (AWS Tools for Windows PowerShell)
Controlling Access to Amazon EC2 Resources

Your security credentials identify you to services in AWS and grant you unlimited use of your AWS resources, such as your Amazon EC2 resources. You can use features of Amazon EC2 and AWS Identity and Access Management (IAM) to allow other users, services, and applications to use your Amazon EC2 resources without sharing your security credentials. You can choose to allow full use or limited use of your Amazon EC2 resources.

Network Access to Your Instance

A security group acts as a firewall that controls the traffic allowed to reach one or more instances. When you launch an instance, you assign it one or more security groups. You add rules to each security group that control traffic for the instance. You can modify the rules for a security group at any time; the new rules are automatically applied to all instances to which the security group is assigned.

For more information, see Authorizing Inbound Traffic for Your Instances (p. 483).

Amazon EC2 Permission Attributes

Your organization might have multiple AWS accounts. Amazon EC2 enables you to specify additional AWS accounts that can use your Amazon Machine Images (AMIs) and Amazon EBS snapshots. These permissions work at the AWS account level only; you can't restrict permissions for specific users within the specified AWS account. All users in the AWS account that you've specified can use the AMI or snapshot.

Each AMI has a LaunchPermission attribute that controls which AWS accounts can access the AMI. For more information, see Making an AMI Public (p. 57).

Each Amazon EBS snapshot has a createVolumePermission attribute that controls which AWS accounts can use the snapshot. For more information, see Sharing Snapshots (p. 563).

IAM and Amazon EC2

IAM enables you to do the following:

- Create users and groups under your AWS account
- Assign unique security credentials to each user under your AWS account
- Control each user's permissions to perform tasks using AWS resources
- Allow the users in another AWS account to share your AWS resources
- Create roles for your AWS account and define the users or services that can assume them
- Use existing identities for your enterprise to grant permissions to perform tasks using AWS resources
By using IAM with Amazon EC2, you can control whether users in your organization can perform a task using specific Amazon EC2 API actions and whether they can use specific AWS resources.

This topic helps you answer the following questions:

• How do I create groups and users in IAM?
• How do I create a policy?
• What IAM policies do I need to carry out tasks in Amazon EC2?
• How do I grant permissions to perform actions in Amazon EC2?
• How do I grant permissions to perform actions on specific resources in Amazon EC2?

Creating an IAM Group and Users

To create an IAM group and users

1. Open the IAM console.
2. From the dashboard, click Create a New Group of Users.
3. On the GROUP NAME page, specify the name of the group.
4. On the PERMISSIONS page, specify the policies for the group. You can select a policy template or create custom policies. For example, for Amazon EC2, one of the following policy templates might meet your needs:
   • Power User Access
   • Read Only Access
   • Amazon EC2 Full Access
   • Amazon EC2 Read Only Access

   For more information about creating custom policies, see IAM Policies for Amazon EC2 (p. 450).
5. On the USERS page, enter one or more user names. If the users will use the CLI or API, select Generate an access key for each User. Click Continue.
6. If you had IAM generate access keys, click Download Credentials or Show User Security Credentials and save the access keys. As indicated on the dialog box, this is your only chance to retrieve and save your secret access key.
7. If the users will use the console, click Users in the navigation pane and do the following for each user:
   a. Select the user.
   b. Click the Security Credentials tab in the details pane.
   c. Under Sign-in Credentials, click Manage Password.
   d. In the Manage Password dialog box, select an option and click Apply.
   e. Click Download Credentials or Show User Security Credentials and save the password.
8. Give each user his or her credentials (access keys and password); this enables them to use services based on the permissions you specified for the IAM group.

For more information about IAM, see the following:

• IAM Policies for Amazon EC2 (p. 450)
IAM Policies for Amazon EC2

By default, IAM users don't have permission to create or modify Amazon EC2 resources, or perform tasks using the Amazon EC2 API. (This means that they also can't do so using the Amazon EC2 console or CLI.) To allow IAM users to create or modify resources and perform tasks, you must create IAM policies that grant IAM users permission to use the specific resources and API actions they'll need, and then attach those policies to the IAM users or groups that require those permissions.

When you attach a policy to a user or group of users, it allows or denies the users permission to perform the specified tasks on the specified resources. For more general information about IAM policies, see Permissions and Policies in the Using IAM guide.

Policy Syntax

An IAM policy is a JSON document that consists of one or more statements. Each statement is structured as follows:

```
{
  "Statement":
    {
      "Effect":"allow",
      "Action":"action",
      "Resource":"arn",
      "Condition":
        {
          "key":"value"
        }
    }
}
```

There are various elements that make up a statement:

- **Effect**: The *effect* can be *allow* or *deny*. By default, IAM users don't have permission to use resources and API actions, so all requests are denied. An explicit allow overrides the default. An explicit deny overrides any allows.
- **Action**: The *action* is the specific API action for which you are granting or denying permission. To learn about specifying *action*, see Actions for Amazon EC2 (p. 451).
• **Resource:** The resource that's affected by the action. Some Amazon EC2 API actions allow you to include specific resources in your policy that can be created or modified by the action. To specify a resource in the statement, you need to use its Amazon Resource Name (ARN). For more information about specifying the `arn` value, see [Amazon Resource Names for Amazon EC2](p. 451). For more information about which API actions support which ARNs, see [Supported Resources and Conditions for Amazon EC2 API Actions](p. 456). If the API action does not support ARNs, use the `*` wildcard to specify that all resources can be affected by the action.

• **Condition:** Conditions are optional. They can be used to control when your policy will be in effect. For more information about specifying conditions for Amazon EC2, see [Condition Keys for Amazon EC2](p. 454).

For more information about example IAM policy statements for Amazon EC2, see [Example Policy Statements for Amazon EC2](p. 463).

### Actions for Amazon EC2

In an IAM policy statement, you can specify any API action from any service that supports IAM. For Amazon EC2, use the following prefix with the name of the API action: `ec2:`. For example: `ec2:RunInstances` and `ec2:CreateImage`.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["ec2:action1", "ec2:action2"]
```

You can also specify multiple actions using wildcards. For example, you can specify all actions whose name begins with the word "Describe" as follows:

```
"Action": "ec2:Describe*"
```

To specify all Amazon EC2 API actions, use the `*` wildcard as follows:

```
"Action": "ec2:*"
```

For a list of Amazon EC2 actions, see [Actions](https://docs.aws.amazon.com/AmazonElasticComputeCloud/latest/APIReference/Welcome.html) in the *Amazon Elastic Compute Cloud API Reference*.

### Amazon Resource Names for Amazon EC2

Each IAM policy statement applies to the resources that you specify using their ARNs.

**Important**

Currently, not all API actions support individual ARNs; we'll add support for additional API actions and ARNs for additional Amazon EC2 resources later. For information about which ARNs you can use with which Amazon EC2 API actions, as well as supported condition keys for each ARN, see [Supported Resources and Conditions for Amazon EC2 API Actions](p. 456).

An ARN has the following general syntax:

```
arn:aws:[service]:[region]:[account]:resourceType/resourcePath
```

- **service**
  - The service (for example, ec2).

- **region**
  - The region for the resource (for example, us-east-1).
**account**
The AWS account ID, with no hyphens (for example, 123456789012).

**resourceType**
The type of resource (for example, instance).

**resourcePath**
A path that identifies the resource. You can use the * wildcard in your paths.

For example, you can indicate a specific instance (i-1a2b3c4d) in your statement using its ARN as follows:

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/i-1a2b3c4d"
```

You can also specify all instances that belong to a specific account by using the * wildcard as follows:

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*"
```

To specify all resources, or if a specific API action does not support ARNs, use the * wildcard in the Resource element as follows:

```
"Resource": "*"
```

The following table describes the ARNs for each type of resource used by the Amazon EC2 API actions.

Where *key-pair-name* is the key pair name (for example, `gsg-keypair`)

Where *nacl-id* is acl-xxxxxxx

Where *eni-id* is eni-xxxxxxx

Placement group | `arn:aws:ec2:region:account:placement-group/placement-group-name`
Where *placement-group-name* is the placement group name (for example, `my-cluster`)

Where *route-table-id* is rtb-xxxxxxx

Where *security-group-id* is sg-xxxxxxx

Snapshot | `arn:aws:ec2:region::snapshot/snapshot-id`
Where *snapshot-id* is snap-xxxxxxx, and *account* isn’t used

Subnet | `arn:aws:ec2:region:account:subnet/subnet-id`
Where *subnet-id* is subnet-xxxxxxx

Where *volume-id* is vol-xxxxxxx

VPC | `arn:aws:ec2:region:account:vpc/vpc-id`
Where *vpc-id* is vpc-xxxxxxx

Where *vpc-peering-connection-id* is pcx-xxxxxxx

Many Amazon EC2 API actions involve multiple resources. For example, `AttachVolume` attaches an Amazon EBS volume to an instance, so an IAM user must have permission to use the volume and the instance. To specify multiple resources in a single statement, separate their ARNs with commas, as follows:

```
"Resource": ["arn1", "arn2"]
```

For more general information about ARNs, see Amazon Resource Names (ARN) and AWS Service Namespaces in the Amazon Web Services General Reference. For more information about the resources that are created or modified by the Amazon EC2 actions, and the ARNs that you can use in your IAM policy statements, see Granting IAM Users Required Permissions for Amazon EC2 Resources in the Amazon Elastic Compute Cloud API Reference.
## Condition Keys for Amazon EC2

In a policy statement, you can optionally specify conditions that control when it is in effect. Each condition contains one or more key-value pairs. Condition keys are not case sensitive. We've defined AWS-wide condition keys, plus additional service-specific condition keys.

If you specify multiple conditions, or multiple keys in a single condition, we evaluate them using a logical AND operation. If you specify a single condition with multiple values for one key, we evaluate the condition using a logical OR operation. For permission to be granted, all conditions must be met.

You can also use placeholders when you specify conditions. For example, you can grant an IAM user permission to use resources with a tag that specifies his or her IAM user name. For more information, see Policy Variables in the *Using IAM* guide.

Amazon EC2 implements the AWS-wide condition keys (see Available Keys), plus the following service-specific condition keys. (We'll add support for additional service-specific condition keys for Amazon EC2 later.)

### Checking that Users Have the Required Permissions

After you've created an IAM policy, we recommend that you check whether it grants users the permissions to use the particular API actions and resources they need before you put the policy into production.

First, create an IAM user for testing purposes, and then attach the IAM policy that you created to the test user. Then, make a request as the test user.

If the action that you are testing creates or modifies a resource, you should make the request using the `DryRun` parameter (or run the CLI command with the `--auth-dry-run` option). In this case, the call completes the authorization check, but does not complete the operation. For example, you can check whether the user can terminate a particular instance without actually terminating it. If the test user has the required permissions, the request returns `DryRunOperation`; otherwise, it returns `UnauthorizedOperation`.

If the policy doesn't grant the user the permissions that you expected, or is overly permissive, you can adjust the policy as needed and retest until you get the desired results.

**Important**

It can take several minutes for policy changes to propagate before they take effect. Therefore, we recommend that you allow five minutes to pass before you test your policy updates.

If an authorization check fails, the request returns an encoded message with diagnostic information. You can decode the message using the `DecodeAuthorizationMessage` action. For more information, see `DecodeAuthorizationMessage` in the AWS Security Token Service API Reference, and `decode-authorization-message` in the AWS Command Line Interface Reference.

### Supported Resources and Conditions for Amazon EC2 API Actions

**Example Policy Statements for Amazon EC2**

The following examples show policy statements that you could use to control the permissions that IAM users have to Amazon EC2. For more examples of IAM policies specific to Amazon VPC, see [Controlling Access to Amazon VPC Resources](#).

- 1: Allow users to list the Amazon EC2 resources that belong to the AWS account (p. 463)
- 2: Allow users to describe, launch, stop, start, and terminate all instances (p. 464)
- 3: Allow users to describe all instances, and stop, start, and terminate only particular instances (p. 464)
- 4: Allow users to manage particular volumes for particular instances (p. 465)
- 5: Allow users to launch instances with a specific configuration (p. 466)
- 6: Working in the Amazon EC2 console (p. 471)

**Example 1: Allow users to list the Amazon EC2 resources that belong to the AWS account**

The following policy grants users permission to use all Amazon EC2 API actions whose names begin with `Describe`. The `Resource` element uses a wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support...
resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Supported Resources and Conditions for Amazon EC2 API Actions (p. 456).

Users don't have permission to perform any actions on the resources (unless another statement grants them permission to do so) because they're denied permission to use API actions by default.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "ec2:Describe*",
        "Resource": "*"
    }]
}
```

**Example 2: Allow users to describe, launch, stop, start, and terminate all instances**

The following policy grants users permission to use the API actions specified in the `Action` element. The `Resource` element uses a * wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Supported Resources and Conditions for Amazon EC2 API Actions (p. 456).

The users don't have permission to use any other API actions (unless another statement grants them permission to do so) because users are denied permission to use API actions by default.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeInstances", "ec2:DescribeImages",
            "ec2:DescribeKeyPairs", "ec2:DescribeSecurityGroups",
            "ec2:DescribeAvailabilityZones",
            "ec2:RunInstances", "ec2:TerminateInstances",
            "ec2:StopInstances", "ec2:StartInstances"
        ],
        "Resource": "*"
    }]
}
```

**Example 3: Allow users to describe all instances, and stop, start, and terminate only particular instances**

The following policy allows users to describe all instances, to start and stop only instances i-123abc12 and i-4c3b2a1, and to terminate only instances in the US East (Northern Virginia) Region (us-east-1) with the resource tag "purpose=test".

The first part of the statement uses a * wildcard for the `Resource` element to indicate that users can specify all resources with the action; in this case, they can list all instances. The * wildcard is also necessary in cases where the API action does not support resource-level permissions (in this case, ec2:DescribeInstances). For more information about which ARNs you can use with which Amazon EC2 API actions, see Supported Resources and Conditions for Amazon EC2 API Actions (p. 456).
The second part of the statement uses resource-level permissions for the `StopInstances` and `StartInstances` actions. The specific instances are indicated by their ARNs in the `Resource` element.

The third part of this statement allows users to terminate all instances in the US East (Northern Virginia) Region (`us-east-1`) that belong to the specified AWS account, but only where the instance has the tag "purpose=test". The `Condition` element qualifies when the policy statement is in effect.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:DescribeInstances"],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": ["ec2:StopInstances", "ec2:StartInstances"],
      "Resource": [
        "arn:aws:ec2:us-east-1:123456789012:instance/i-123abc12",
        "arn:aws:ec2:us-east-1:123456789012:instance/i-4c3b2a1"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "ec2:TerminateInstances",
      "Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/purpose": "test"
        }
      }
    }
  ]
}
```

**Example 4. Allow users to manage particular volumes for particular instances**

When an API action requires a caller to specify multiple resources, you must create a policy statement that allows users to access all required resources. If you need to use a `Condition` element with one or more of these resources, you must create multiple statements as shown in this example.

The following policy allows users to attach volumes with the tag "volume_user=iam-user-name" to instances with the tag "department=dev", and to detach those volumes from those instances. If you attach this policy to an IAM group, the `aws:username` policy variable gives each IAM user in the group permission to attach or detach volumes from the instances with a tag named `volume_user` that has his or her IAM user name as a value.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:AttachVolume",
      "ec2:DetachVolume"
    ],
    "Condition": {
      "StringEquals": {
        "ec2:ResourceTag/volume_user": "iam-user-name"
      }
    }
  }]
}
```
Example 5: Allow users to launch instances with a specific configuration

The RunInstances API action launches one or more instances. RunInstances requires an AMI and creates an instance; and users can specify a key pair and security group in the request. Launching into EC2-VPC requires a subnet, and creates a network interface. Launching from an Amazon EBS-backed AMI creates a volume. Therefore, the user must have permission to use these Amazon EC2 resources. The caller can also configure the instance using optional parameters to RunInstances, such as the instance type and a subnet. You can create a policy statement that requires users to specify an optional parameter, or restricts users to particular values for a parameter. The examples in this section demonstrate some of the many possible ways that you can control the configuration of an instance that a user can launch.

Note that by default, users don't have permission to describe, start, stop, or terminate the resulting instances. One way to grant the users permission to manage the resulting instances is to create a specific tag for each instance, and then create a statement that enables them to manage instances with that tag. For more information, see Example 3: Allow users to stop and start only particular instances (p. 464).

a. AMI

The following policy allows users to launch instances using only the AMIs that have the specified tag, "department=dev", associated with them. The users can't launch instances using other AMIs because the Condition element of the first statement requires that users specify an AMI that has this tag. The users also can't launch into a subnet, as the policy does not grant permissions for the subnet and network interface resources. They can, however, launch into EC2-Classic. The second statement uses a wildcard to enable users to create instance resources, and requires users to specify the key pair project_keypair and the security group sg-1a2b3c4d. Users are still able to launch instances without a key pair.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AttachVolume",
        "ec2:DetachVolume"
      ],
      "Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*",
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/department": "dev"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AttachVolume",
        "ec2:DetachVolume"
      ],
      "Condition": {
        "StringEquals": {
          "ec2:ResourceTag/volume_user": "${aws:username}""
Alternatively, the following policy allows users to launch instances using only the specified AMIs, ami-9e1670f7 and ami-45cf5c3c. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so), and the users can't launch an instance into a subnet.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": [
      "arn:aws:ec2:region::image/ami-9e1670f7",
      "arn:aws:ec2:region::image/ami-45cf5c3c",
      "arn:aws:ec2:region:account:instance/**",
      "arn:aws:ec2:region:account:volume/**",
      "arn:aws:ec2:region:account:key-pair/project_keypair",
      "arn:aws:ec2:region:account:security-group/sg-1a2b3c4d"
    ]
  }]
}
```

Alternatively, the following policy allows users to launch instances from all AMIs owned by Amazon. The Condition element of the first statement tests whether ec2:Owner is amazon. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so). The users are able to launch an instance into a subnet.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": [
      "arn:aws:ec2:region::image/ami-*"
    ]
  }]
}
```
b. Instance type

The following policy allows users to launch instances using only the \texttt{t1.micro} or \texttt{m1.small} instance type, which you might do to control costs. The users cannot launch larger instances because the \texttt{Condition} element of the first statement tests whether \texttt{ec2:InstanceType} is either \texttt{t1.micro} or \texttt{m1.small}.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:account:instance/**",
        "arn:aws:ec2:region:account:subnet/**",
        "arn:aws:ec2:region:account:volume/**",
        "arn:aws:ec2:region:account:key-pair/**",
        "arn:aws:ec2:region:account:security-group/**"
      ],
      "Condition": {
        "StringEquals": {
          "ec2:InstanceType": ["t1.micro", "m1.small"]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:account:subnet/**",
        "arn:aws:ec2:region:account:volume/**",
        "arn:aws:ec2:region:account:key-pair/**",
        "arn:aws:ec2:region:account:security-group/**"
      ]
    }
  ]
}
```
c. Subnet

The following policy allows users to launch instances using only the specified subnet, subnet-12345678. The group can’t launch instances into any another subnet (unless another statement grants the users permission to do so). Users are still able to launch instances into EC2-Classic.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": [
      "arn:aws:ec2:region:account:instance/**",
      "arn:aws:ec2:region:account:volume/**",
      "arn:aws:ec2:region::image/ami-*",
      "arn:aws:ec2:region:account:security-group/**
    ]
  }]
}
```

Alternatively, you could create a policy that denies users permission to launch an instance into any other subnet. The statement does this by denying permission to create a network interface, except where subnet subnet-12345678 is specified. This denial overrides any other policies that are created to allow launching instances into other subnets. Users are still able to launch instances into EC2-Classic.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Deny",
    "Action": "ec2:RunInstances",
    "Resource": [
    ],
    "Condition": {
      "ArnNotEquals": {
    }
  }],
  "Effect": "Allow",
  "Action": "ec2:RunInstances",
  "Resource": [
    "arn:aws:ec2:region::image/ami-*",
    "arn:aws:ec2:region:account:instance/**",
    "arn:aws:ec2:region:account:subnet/**",
    "arn:aws:ec2:region:account:volume/**",
    "arn:aws:ec2:region:account:security-group/**
  ]
}
```
Example 6: Working in the Amazon EC2 console

You can use IAM policies to grant users permissions to view and work with specific resources in the Amazon EC2 console. You can use the example policies above; however, they are designed for requests that are made with the AWS CLI, the Amazon EC2 CLI, or an AWS SDK. The console uses additional API actions for its features, so these policies may not work as expected. For example, a user that has permission to use only the DescribeVolumes API action will encounter errors when trying to view volumes in the console. This section demonstrates policies that enable users to work with specific parts of the console.

**Note**

To help you work out which API actions are required to perform tasks in the console, you can use a service such as AWS CloudTrail. For more information, see the AWS CloudTrail User Guide. If your policy does not grant permission to create or modify a specific resource, the console displays an encoded message with diagnostic information. You can decode the message using the DecodeAuthorizationMessage API action for AWS STS, or the decode-authorization-message command in the AWS CLI.

**a. Read-only access**

To allow users to view all resources in the Amazon EC2 console, you can use the same policy as the example above: 1: Allow users to list the Amazon EC2 resources that belong to the AWS account (p. 463). Users cannot perform any actions on those resources or create new resources, unless another statement grants them permission to do so.

Alternatively, you can provide read-only access to a subset of resources. To do this, replace the * wildcard in the ec2:Describe API action with specific ec2:Describe actions for each resource. The following policy allows users to view all instances, AMIs, and snapshots in the Amazon EC2 console. The ec2:DescribeTags action allows users to view public AMIs; you can remove this action if you want users to view only private AMIs.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [ "ec2:DescribeInstances", "ec2:DescribeImages",
                    "ec2:DescribeTags", "ec2:DescribeSnapshots"
                ],
        "Resource": "*"
    }]
}
```

**Note**

Currently, the Amazon EC2 ec2:Describe* API actions do not support resource-level permissions, so you cannot control which individual resources users can view in the console. Therefore, the * wildcard is necessary in the Resource element of the above statement. For more information about which ARNs you can use with which Amazon EC2 API actions, see Supported Resources and Conditions for Amazon EC2 API Actions (p. 456).

**b. Using the EC2 launch wizard**

The Amazon EC2 launch wizard is a series of screens with options to configure and launch an instance. Your policy must include permission to use the API actions that allow users to work with the wizard’s options. If your policy does not include permission to use those actions, some items in the wizard cannot load properly, and users cannot complete a launch.
To complete a launch successfully, users must be given permission to use the ec2:RunInstances API action, and at least the following API actions:

- **ec2:DescribeImages:** To view and select an AMI.
- **ec2:DescribeVPCs:** To view the available network options, which are EC2-Classic and a list of VPCs. This is required even if you are not launching into a VPC.
- **ec2:DescribeSubnets:** If launching into a VPC, to view all available subnets for the chosen VPC.
- **ec2:DescribeSecurityGroups:** To view the security groups page in the wizard. Users can select an existing security group.
- **ec2:DescribeKeyPairs or ec2:CreateKeyPair:** To select an existing key pair, or create a new one.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeInstances",
      "ec2:DescribeImages",
      "ec2:DescribeKeyPairs",
      "ec2:DescribeVpcs",
      "ec2:DescribeSubnets",
      "ec2:DescribeSecurityGroups"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": "*"
  }
}
```

You can add API actions to your policy to provide more options for users, for example:

- **ec2:DescribeAvailabilityZones:** If launching into EC2-Classic, to view and select a specific Availability Zone.
- **ec2:DescribeNetworkInterfaces:** If launching into a VPC, to view and select existing network interfaces for the selected subnet.
- **ec2:CreateSecurityGroup:** To create a new security group; for example, to create the wizard's suggested launch-wizard-x security group. However, this action alone only creates the security group; it does not add or modify any rules. To add inbound rules, users must be granted permission to use the ec2:AuthorizeSecurityGroupIngress API action. To add outbound rules to VPC security groups, users must be granted permission to use the ec2:AuthorizeSecurityGroupEgress API action. To modify or delete existing rules, users must be granted permission to use the relevant ec2:RevokeSecurityGroup* API action.
- **ec2:CreateTags:** To add a tag to the instance. By default, the launch wizard attempts to add a tag with a key of Name to an instance. Users that do not have permission to use this action will encounter a warning that this tag could not be applied to an instance; however, this does not affect the success of the launch, so you should only grant users permission to use this action if it's absolutely necessary.

**Important**

Be careful about granting users permission to use the ec2:CreateTags action. This limits your ability to use the ec2:ResourceTag condition key to restrict the use of other resources; users can change a resource's tag in order to bypass those restrictions.
Currently, the Amazon EC2 Describe* API actions do not support resource-level permissions, so you cannot restrict which individual resources users can view in the launch wizard. However, you can apply resource-level permissions on the `ec2:RunInstances` API action to restrict which resources users can use to launch an instance. The launch fails if users select options that they are not authorized to use.

The following policy allows users to launch `m1.small` instances using AMIs owned by Amazon, and only into a specific subnet (`subnet-1a2b3c4d`). Users can only launch in the `sa-east-1` region. If users select a different region, or select a different instance type, AMI, or subnet in the launch wizard, the launch fails.

The first part of the statement grants users permission to view the options in the launch wizard, as demonstrated in the example above. The second part of the statement grants users permission to use the network interface, volume, key pair, security group, and subnet resources for the `ec2:RunInstances` action, which are required to launch an instance into a VPC. For more information about using the `ec2:RunInstances` action, see 5: Allow users to launch instances with a specific configuration (p. 466). The third and fourth parts of the statement grant users permission to use the instance and AMI resources respectively, but only if the instance is an `m1.small` instance, and only if the AMI is owned by Amazon.
c. Working with volumes

The following policy grants users permission to view and create volumes, and attach and detach volumes to specific instances.
Users can attach any volume to instances that have the tag "purpose=test", and also detach volumes from those instances. To attach a volume using the Amazon EC2 console, it is helpful for users to have permission to use the `ec2:DescribeInstances` action, as this allows them to select an instance from a pre-populated list in the **Attach Volume** dialog box. However, this also allows users to view all instances on the **Instances** page in the console, so you can omit this action.

In the first part of the statement, the `ec2:DescribeVolumeStatus` and `ec2:DescribeAvailabilityZones` actions are necessary to ensure that volumes display correctly in the console.

```json
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeVolumes", "ec2:DescribeVolumeStatus",
         "ec2:DescribeAvailabilityZones", "ec2:CreateVolume",
         "ec2:DescribeInstances"
      ],
      "Resource": "*"
   },
   { "Effect": "Allow",
     "Action": [ "ec2:AttachVolume", "ec2:DetachVolume" ],
     "Condition": { "StringEquals": { "ec2:ResourceTag/purpose": "test" } }
   },
   { "Effect": "Allow",
     "Action": [ "ec2:AttachVolume", "ec2:DetachVolume" ],
}
```

d. Working with security groups

The following policy grants users permission to view security groups in the Amazon EC2 console, and to add and remove inbound and outbound rules for existing security groups that have the tag `Department=Test`.

**Note**

You can't modify outbound rules for EC2-Classic security groups. For more information about security groups, see Amazon EC2 Security Groups (p. 440).

In the first part of the statement, the `ec2:DescribeTags` action allows users to view tags in the console, which makes it easier for users to identify the security groups that they are allowed to modify.
You can create a policy that allows users to work with the Create Security Group dialog box in the Amazon EC2 console. To use this dialog box, users must be granted permission to use at least the following API actions:

- ec2:CreateSecurityGroup: To create a new security group.
- ec2:DescribeVpcs: To view a list of existing VPCs in the VPC list. This action is required even if you are not creating a security group for a VPC.

With these permissions, users can create a new security group successfully, but they cannot add any rules to it. To work with rules in the Create Security Group dialog box, you can add the following API actions to your policy:

- ec2:AuthorizeSecurityGroupIngress: To add inbound rules.
- ec2:AuthorizeSecurityGroupEgress: To add outbound rules to VPC security groups.
- ec2:RevokeSecurityGroupIngress: To modify or delete existing inbound rules. This is useful if you want to allow users to use the Copy to new feature in the console. This feature opens the Create Security Group dialog box and populates it with the same rules as the security group that was selected.
- ec2:RevokeSecurityGroupEgress: To modify or delete outbound rules for VPC security groups. This is useful to allow users to modify or delete the default outbound rule that allows all outbound traffic.
- ec2:DeleteSecurityGroup: To cater for scenarios where invalid rules cannot be saved. If a user creates a security group with an invalid rule, the console first creates the security group, then attempts to add the rules to it. After that fails, the security group is deleted. The user remains in the Create Security Group dialog box, where an error is displayed. The rules remain listed, so the user can correct the invalid rule and try to create the security group again. This API action is not required, but if a user is not granted permission to use it and attempts to create a security group with invalid rules, the security group is created without any rules, and the user must add them afterward.
Currently, the `ec2:CreateSecurityGroup` API action does not support resource-level permissions; however, you can apply resource-level permissions to the `ec2:AuthorizeSecurityGroupIngress` and `ec2:AuthorizeSecurityGroupEgress` actions to control how users can create rules.

The following policy grants users permission to use the Create Security Group dialog box, and to create inbound and outbound rules for security groups that are associated with a specific VPC (vpc-1a2b3c4d). Users can create security groups for EC2-Classic or another VPC, but they cannot add any rules to them. Similarly, users cannot add any rules to any existing security group that's not associated with VPC vpc-1a2b3c4d. Users are also granted permission to view all security groups in the console. This makes it easier for users to identify the security groups to which they can add inbound rules.

This policy also grants users permission to delete security groups that are associated with VPC vpc-1a2b3c4d.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeSecurityGroups", "ec2:CreateSecurityGroup", "ec2:DescribeVpcs"
    ],
    "Resource": "*"
  },
  { "Effect": "Allow",
    "Action": [
    ],
    "Condition":{
      "ArnEquals": {
        "ec2:Vpc": "arn:aws:ec2:region:111122223333:vpc/vpc-1a2b3c4d"
      }
    }
  }
}
```

## IAM Roles for Amazon EC2

Applications must sign their API requests with AWS credentials. Therefore, if you are an application developer, you need a strategy for managing credentials for your applications that run on EC2 instances. For example, you can securely distribute your AWS credentials to the instances, enabling the applications on those instances to use your credentials to sign requests, while protecting them from other users. However, it's challenging to securely distribute credentials to each instance, especially those that AWS creates on your behalf, such as Spot Instances or instances in Auto Scaling groups. You must also be able to update the credentials on each instance when you rotate your AWS credentials.

We designed IAM roles so that your applications can securely make API requests from your instances, without requiring you to manage the security credentials that the applications use. Instead of creating and distributing your AWS credentials, you can delegate permission to make API requests using IAM roles as follows:

1. Create an IAM role.
2. Define which accounts or AWS services can assume the role.
3. Define which API actions and resources the application can use after assuming the role.
4. Specify the role when you launch your instances.
5. Have the application retrieve a set of temporary credentials and use them.

For example, you can use IAM roles to grant permissions to applications running on your instances that needs to use a bucket in Amazon S3.

**Note**

Amazon EC2 uses an instance profile as a container for an IAM role. When you create an IAM role using the console, the console creates an instance profile automatically and gives it the same name as the role it corresponds to. If you use the AWS CLI, API, or an AWS SDK to create a role, you create the role and instance profile as separate actions, and you might give them different names. To launch an instance with an IAM role, you specify the name of its instance profile. When you launch an instance using the Amazon EC2 console, you can select a role to associate with the instance; however, the list that's displayed is actually a list of instance profile names. For more information, see Instance Profiles in the Using IAM.

You can specify permissions for IAM roles by creating a policy in JSON format. These are similar to the policies that you create for IAM users. If you make a change to a role, the change is propagated to all instances, simplifying credential management.

**Note**

You can't assign a role to an existing instance; you can only specify a role when you launch a new instance.

For more information about creating and using IAM roles, see Roles in the Using IAM guide.

### Retrieving Security Credentials from Instance Metadata

An application on the instance retrieves the security credentials provided by the role from the instance metadata item `iam/security-credentials/role-name`. The application is granted the permissions for the actions and resources that you've defined for the role through the security credentials associated with the role. These security credentials are temporary and we rotate them automatically. We make new credentials available at least five minutes prior to the expiration of the old credentials.

**Warning**

If you use services that use instance metadata with IAM roles, ensure that you don't expose your credentials when the services make HTTP calls on your behalf. The types of services that could expose your credentials include HTTP proxies, HTML/CSS validator services, and XML processors that support XML inclusion.

The following command retrieves the security credentials for an IAM role named `s3access`.

```
```

The following is example output.
Granting an IAM User Permission to Launch an Instance with an IAM Role

To enable an IAM user to launch an instance with an IAM role, you must grant the user permission to pass the role to the instance.

For example, the following IAM policy grants users permission to launch an instance with the IAM role named s3access.

```json
{

"Version": "2012-10-17",
"Statement": [

{"Effect": "Allow",
"Action": "iam:PassRole",
"Resource": "arn:aws:iam::123456789012:role/s3access"

}]

```

Alternatively, you could grant IAM users access to all your roles by specifying the resource as "*" in this policy. However, consider whether users who launch instances with your roles (ones that exist or that you'll create later on) might be granted permissions that they don't need or shouldn't have.

For more information, see Permissions Required for Using Roles with Amazon EC2 in the Using IAM guide.

Launching an Instance with an IAM Role Using the Console

You must create an IAM role before you can launch an instance with that role.

Important
After you create an IAM role, it may take several seconds for the permissions to propagate. If your first attempt to launch an instance with a role fails, wait a few seconds before trying again. For more information, see Troubleshooting Working with Roles in the Using IAM guide.

To create an IAM role using the IAM console

1. Open the IAM console.
2. In the navigation pane, click Roles, and then click Create New Role.
3. On the first CONFIGURE ROLE page, enter a name for the role and click Continue.
4. On the second CONFIGURE ROLE page, click Select next to Amazon EC2.
5. On the **SET PERMISSIONS** page, specify the policies for the group. You can select a policy template or create custom policies. For example, for Amazon EC2, one of the following policy templates might meet your needs:

- Power User Access
- Read Only Access
- Amazon EC2 Full Access
- Amazon EC2 Read Only Access

For more information about creating custom policies, see [IAM Policies for Amazon EC2](#) (p. 450).

6. On the second **SET PERMISSIONS** page, you can replace the automatically generated policy name with a name of your choice. Check the details in the policy document, and click **Continue**.

7. Review the role information, edit the role as needed, and then click **Create Role**.

### To launch an instance with an IAM role

1. Open the Amazon EC2 console.
2. On the dashboard, click **Launch Instance**.
3. Select an AMI, then select an instance type and click **Next: Configure Instance Details**.
4. On the **Configure Instance Details** page, select the IAM role you created from the **IAM role** list.

   **Note**
   
   The **IAM role** list displays the name of the instance profile that you created when you created your IAM role. If you created your IAM role using the console, the instance profile was created for you and given the same name as the role. If you created your IAM role using the AWS CLI, API, or an AWS SDK, you may have named your instance profile differently to your IAM role.

5. Configure any other details, then follow the instructions through the rest of the wizard, or click **Review and Launch** to accept default settings and go directly to the **Review Instance Launch** page.

6. Review your settings, then click **Launch** to choose a key pair and launch your instance.

7. If you are using the Amazon EC2 API actions in your application, retrieve the AWS security credentials made available on the instance and use them to sign the requests. Note that the AWS SDK does this for you.

   ```
   ```

### Launching an Instance with an IAM Role Using the AWS CLI

You must create an IAM role before you can launch an instance with that role.

**Important**

After you create an IAM role, it may take several seconds for the permissions to propagate. If your first attempt to launch an instance with a role fails, wait a few seconds before trying again. For more information, see [Troubleshooting Working with Roles](#) in the **Using IAM** guide.

### To create an IAM role using the AWS CLI

- Create an IAM role with a policy that allows the role to use an Amazon S3 bucket.
  
  a. Create the following trust policy and save it in a text file named `ec2-role-trust-policy.json`.
b. Create the `s3access` role. You'll specify the trust policy you created.

```bash
aws iam create-role --role-name s3access --assume-role-policy-document file://ec2-role-trust-policy.json
```

```
{
   "Role": {
      "AssumeRolePolicyDocument": {
         "Version": "2012-10-17",
         "Statement": [
            {
               "Action": "sts:AssumeRole",
               "Effect": "Allow",
               "Principal": {
                  "Service": "ec2.amazonaws.com"
               }
            }
         ],
         "RoleId": "AROAIIZKPBKS2LEXAMPLE",
         "CreateDate": "2013-12-12T23:46:37.247Z",
         "RoleName": "s3access",
         "Path": "/",
         "Arn": "arn:aws:iam::123456789012:role/s3access"
      }
   }
}
```

c. Create an access policy and save it in a text file named `ec2-role-access-policy.json`. For example, this policy grants administrative permissions for Amazon S3 to applications running on the instance.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["s3:*"],
         "Resource": ["*"]
      }
   ]
}
```

d. Attach the access policy to the role.
e. Create an instance profile named s3access-profile.

```bash
aws iam create-instance-profile --instance-profile-name S3-Permissions
{
    "InstanceProfile": {
        "InstanceProfileId": "AIPAJTLBPJLEGEXAMPLE",
        "Roles": [],
        "CreateDate": "2013-12-12T23:53:34.093Z",
        "InstanceProfileName": "S3-Permissions",
        "Path": "/",
        "Arn": "arn:aws:iam::123456789012:instance-profile/S3-Permissions"
    }
}
```

f. Add the s3access role to the s3access-profile instance profile.

```bash
aws iam add-role-to-instance-profile --instance-profile-name S3-Permissions --role-name s3access
```

For more information about these commands, see create-role, put-role-policy, and create-instance-profile in the AWS Command Line Interface Reference.

To launch an instance with an IAM role using the AWS CLI

1. Launch an instance using the instance profile. The following example shows how to launch a t1.micro instance with the instance profile.

```bash
aws ec2 run-instances --instance-type t1.micro --image-id ami-e565ba8c --iam-instance-profile Name="S3-Permissions" --key-name my-key-pair --security-groups my-security-group
```

For more information, see run-instances in the AWS Command Line Interface Reference.

2. If you are using the Amazon EC2 API actions in your application, retrieve the AWS security credentials made available on the instance and use them to sign the requests. Note that the AWS SDK does this for you.

```bash
```

Launching an Instance with an IAM Role Using an AWS SDK

If you use an AWS SDK to write your application, you automatically get temporary security credentials from the role associated with the current instance. The AWS SDK documentation includes walkthroughs that show how an application can use security credentials from a IAM role to read an Amazon S3 bucket.

For more information, see the following topics in the SDK documentation:
Authorizing Inbound Traffic for Your Instances

To enable network access to your instance, you must allow inbound traffic to your instance. To open a port for inbound traffic, add a rule to a security group that you associated with your instance when you launched it.

The following table describes the rule you need to set up to authorize traffic. The documentation shows you how to authorize traffic from your computer's public IP address. To allow traffic from additional IP address ranges, add another rule for each range you need to authorize.

<table>
<thead>
<tr>
<th>Your Instance</th>
<th>Protocol</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>SSH (port 22)</td>
<td>Adding a Rule for Inbound SSH Traffic to a Linux Instance (p. 483)</td>
</tr>
<tr>
<td>Windows</td>
<td>RDP (port 3389)</td>
<td>Adding a Rule for Inbound RDP Traffic to a Windows Instance (p. 484)</td>
</tr>
</tbody>
</table>

Before You Start

Decide who requires access to your instance; for example, a single host or a specific network that you trust. In this case, we use your local system's public IP address. You can get the public IP address of your local computer using a service. For example, we provide the following service: http://checkip.amazonaws.com/. To locate another service that provides your IP address, use the search phrase “what is my IP address”. If you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

**Caution**

If you use 0.0.0.0/0, you enable all IP addresses to access your instance using SSH or RDP. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you'll authorize only a specific IP address or range of addresses to access your instance.

For more information about security groups, see Amazon EC2 Security Groups (p. 440).

Adding a Rule for Inbound SSH Traffic to a Linux Instance

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your instance from your IP address using SSH.

**To add a rule to a security group for inbound SSH traffic using the console**

1. In the navigation pane of the Amazon EC2 console, click Instances. Select your instance and look at the Description tab; Security groups lists the security groups that are associated with the instance. Click view rules to display a list of the rules that are in effect for the instance.
2. In the navigation pane, click Security Groups. Select one of the security groups associated with your instance.
3. In the details pane, on the **Inbound** tab, click **Edit**. In the dialog, click **Add Rule**, and then select **SSH** from the **Type** list.

4. In the **Source** field, specify the public IP address of your computer, in CIDR notation. For example, if your IP address is 203.0.113.25, specify 203.0.113.25/32 to list this single IP address in CIDR notation. If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24.

   For information about finding your IP address, see Before You Start (p. 483).

5. Click **Save**.

**To add a rule to a security group using the command line**

You can use one of the following commands. Be sure to run this command on your local system, not on the instance itself. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- **authorize-security-group-ingress** (AWS CLI)
- **ec2-authorize** (Amazon EC2 CLI)
- **Grant-EC2SecurityGroupIngress** (AWS Tools for Windows PowerShell)

**Adding a Rule for Inbound RDP Traffic to a Windows Instance**

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your Windows instance from your IP address using RDP.

**To add a rule to a security group for inbound RDP traffic using the console**

1. In the navigation pane of the Amazon EC2 console, click **Instances**. Select your instance and look at the **Description** tab; **Security groups** lists the security groups that are associated with the instance. Click **view rules** to display a list of the rules that are in effect for the instance.

2. In the navigation pane, click **Security Groups**. Select one of the security groups associated with your instance.

3. In the details pane, on the **Inbound** tab, click **Edit**. In the dialog, click **Add Rule**, and then select **RDP** from the **Type** list.

4. In the **Source** field, specify the public IP address of your computer, in CIDR notation. For example, if your IP address is 203.0.113.25, specify 203.0.113.25/32 to list this single IP address in CIDR notation. If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24.

   For information about finding your IP address, see Before You Start (p. 483).

5. Click **Save**.

**To add a rule to a security group using the command line**

You can use one of the following commands. Be sure to run this command on your local system, not on the instance itself. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- **authorize-security-group-ingress** (AWS CLI)
- **ec2-authorize** (Amazon EC2 CLI)
- **Grant-EC2SecurityGroupIngress** (AWS Tools for Windows PowerShell)
Assigning a Security Group to an Instance

You can assign a security group to an instance when you launch the instance. When you add or remove rules, those changes are automatically applied to all instances to which you’ve assigned the security group.

After you launch an instance in EC2-Classic, you can’t change its security groups. After you launch an instance in a VPC, you can change its security groups. For more information, see Changing an Instance’s Security Groups in the Amazon Virtual Private Cloud User Guide.

Amazon EC2 and Amazon Virtual Private Cloud (VPC)

Amazon Virtual Private Cloud (Amazon VPC) enables you to define a virtual network in your own logically isolated area within the Amazon Web Services (AWS) cloud, known as a virtual private cloud (VPC). You can launch your AWS resources, such as instances, into your VPC. Your VPC closely resembles a traditional network that you might operate in your own datacenter, with the benefits of using AWS’s scalable infrastructure. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the Internet. You can connect your VPC to your own corporate datacenter, making the AWS cloud an extension of your datacenter. To protect the resources in each subnet, you can use multiple layers of security, including security groups and network access control lists. For more information, see Amazon Virtual Private Cloud User Guide.

Benefits of Using a VPC

By launching your instances into a VPC instead of EC2-Classic, you gain the ability to:

• Assign static private IP addresses to your instances that persist across starts and stops
• Assign multiple IP addresses to your instances
• Define network interfaces, and attach one or more network interfaces to your instances
• Change security group membership for your instances while they’re running
• Control the outbound traffic from your instances (egress filtering) in addition to controlling the inbound traffic to them (ingress filtering)
• Add an additional layer of access control to your instances in the form of network access control lists (ACL)
• Run your instances on single-tenant hardware

Differences Between EC2-Classic and EC2-VPC

Instances run in one of two supported platforms: EC2-Classic and EC2-VPC. Your AWS account is capable of launching instances either into both platforms or only into EC2-VPC, on a region by region basis. If you can launch instances only into EC2-VPC, we create a default VPC for you. A default VPC combines the benefits of the advanced features provided by EC2-VPC with the ease of use of EC2-Classic. For more information, see Supported Platforms.

The following table summarizes the differences between instances launched in EC2-Classic, instances launched in a default VPC, and instances launched in a nondefault VPC.

### Supported Platforms in the Amazon EC2 Console

The Amazon EC2 console indicates which platforms you can launch instances into for the selected region, and whether you have a default VPC in that region.

Verify that the region you'll use is selected in the navigation bar. On the Amazon EC2 console dashboard, look for **Supported Platforms** under **Account Attributes**. If there are two values, EC2 and VPC, you can launch instances into either platform. If there is one value, VPC, you can launch instances only into EC2-VPC.

If you can launch instances only into EC2-VPC, we create a default VPC for you. Then, when you launch an instance, we launch it into your default VPC, unless you create a nondefault VPC and specify it when you launch the instance.
EC2-VPC

The dashboard displays the following under **Account Attributes** to indicate that the account supports only the EC2-VPC platform, and has a default VPC with the identifier `vpc-1a2b3c4d`.

If your account supports only EC2-VPC, you can select a VPC from the **Network** list, and a subnet from the **Subnet** list when you launch an instance using the launch wizard.

EC2-Classic, EC2-VPC

The dashboard displays the following under **Account Attributes** to indicate that the account supports both the EC2-Classic and EC2-VPC platforms.

If your account supports EC2-Classic and EC2-VPC, you can launch into EC2-Classic using the launch wizard by selecting **Launch into EC2-Classic** from the **Network** list. To launch into a VPC, you can select a VPC from the **Network** list, and a subnet from the **Subnet** list.

For more information about how you can tell which platforms you can launch instances into, see **Detecting Your Supported Platforms** in the *Amazon Virtual Private Cloud User Guide*.

**Differences Between Instances in EC2-Classic and EC2-VPC**

With EC2-Classic, we assign each instance a private IP address from a shared private IP address range. We also assign each instance a public IP address from Amazon's pool of public IP addresses. Instances access the Internet directly through the AWS network edge.

With EC2-VPC, we assign each instance a private IP address from the private IP address range of your VPC. You can control the IP address range, subnets, routing, network gateways, network ACLs, and security groups for your VPC. You can specify whether your instance receives a public IP address during launch. Instances with public IP addresses or Elastic IP addresses can access the Internet through a logical Internet gateway attached to the AWS network edge. For more information about EC2-VPC, see **What is Amazon VPC?** in the *Amazon Virtual Private Cloud User Guide*.

The following diagram shows instances in each platform. Note the following:

- Instances C1, C2, C3, and C4 are in the EC2-Classic platform. C1 and C2 were launched by one account, and C3 and C4 were launched by a different account. These instances can communicate with each other, can access the Internet directly, and can access other services such as Amazon Simple Storage Service (Amazon S3).
- Instances V1 and V2 are in different subnets in the same VPC in the EC2-VPC platform. They were launched by the account that owns the VPC; no other account can launch instances in this VPC. These instances can communicate with each other and can access the following through the Internet gateway: instances in EC2-Classic, other services (such as Amazon S3), and the Internet.
Amazon EC2 Instance IP Addressing

We provide your instances with IP addresses and DNS hostnames. These can vary depending on whether you launched the instance in the EC2-Classic platform or in a virtual private cloud (VPC).

For more information about the differences between EC2-Classic and EC2-VPC, see Amazon EC2 and Amazon Virtual Private Cloud (VPC) (p. 485).

For information about the EC2-Classic and EC2-VPC platforms, see Supported Platforms (p. 487). For information about Amazon VPC, see What is Amazon VPC? in the Amazon Virtual Private Cloud User Guide.
Private Addresses and Internal DNS Hostnames

You can use private IP addresses and internal DNS hostnames for communication between instances in the same network (EC2-Classic or a VPC). Private IP addresses are not reachable from the Internet. For more information about private IP addresses, see RFC 1918.

When you launch an instance, we allocate a private IP address for the instance using DHCP.

Each instance that you launch into a VPC has a default network interface. The network interface specifies the primary private IP address for the instance. If you don't select a primary private IP address, we select an available IP address in the subnet's range. You can specify additional private IP addresses, known as secondary private IP addresses. Unlike primary private IP addresses, secondary private IP addresses can be reassigned from one instance to another. For more information, see Multiple Private IP Addresses (p. 494).

Each instance is provided an internal DNS hostname that resolves to the private IP address of the instance in EC2-Classic or your VPC. We can't resolve the DNS hostname outside the network that the instance is in.

If you create a custom firewall configuration in EC2-Classic, you must allow inbound traffic from port 53 (with a destination port from the ephemeral range) from the address of the Amazon DNS server; otherwise, internal DNS resolution from your instances fails. If your firewall doesn't automatically allow DNS query responses, then you'll need to allow traffic from the IP address of the Amazon DNS server. To get the IP address of the Amazon DNS server on Linux, use the following command: `grep nameserver /etc/resolv.conf`. To get the IP address of the Amazon DNS Server on Windows, use the following command: `ipconfig /all | findstr /c:"DNS Servers"`.

For instances launched in EC2-Classic, a private IP address is associated with the instance until it is stopped or terminated.

For instances launched in a VPC, a private IP address remains associated with the network interface when the instance is stopped and restarted, and is released when the instance is terminated.

Public IP Addresses and External DNS Hostnames

You can use public IP addresses and external DNS hostnames for communication between your instances and the Internet or other AWS products, such as Amazon Simple Storage Service (Amazon S3). Public IP addresses are reachable from the Internet.

When you launch an instance in EC2-Classic, we automatically assign a public IP address to the instance. When you launch an instance into EC2-VPC, you can control whether your instance receives a public IP address. The public IP address is assigned to the eth0 network interface (the primary network interface).

A public IP address is assigned to your instance from Amazon’s pool of public IP addresses, and is not associated with your AWS account. When a public IP address is disassociated from your instance, it is released back into the public IP address pool, and you cannot reuse it.
You cannot manually associate or disassociate a public IP address from your instance. Instead, in certain cases, we release the public IP address from your instance, or assign it a new one:

- We release the public IP address for your instance when it’s stopped or terminated. Your stopped instance receives a new public IP address when it’s restarted.
- We release the public IP address for your instance when you associate an Elastic IP address (EIP) with your instance, or when you associate an EIP with the primary network interface (eth0) of your instance in a VPC. When you disassociate the EIP from your instance, it receives a new public IP address.
- If the public IP address of your instance in a VPC has been released, it will not receive a new one if there is more than one network interface attached to your instance.

If you require a persistent public IP address that can be associated to and from instances as you require, use an Elastic IP address (EIP) instead. You can allocate your own EIP, and associate it to your instance. For more information, see Elastic IP Addresses (EIP) (p. 498).

We don’t automatically assign a public IP address to an instance that you launch in a nondefault subnet. Therefore, if you want an instance in a nondefault subnet to communicate with the Internet, you must either enable the public IP addressing feature during launch, or associate an Elastic IP address with the primary or any secondary private IP address assigned to the network interface for the instance.

We provide each instance that has a public IP address with an external DNS hostname. We resolve an external DNS hostname to the public IP address of the instance outside the network of the instance, and to the private IP address of the instance from within the network of the instance. If your instance is in a VPC and you assign it an Elastic IP address, it receives a DNS hostname if DNS hostnames are enabled. For more information, see Using DNS with Your VPC in the Amazon Virtual Private Cloud User Guide.

The private IP address and public IP address for an instance are directly mapped to each other through network address translation (NAT). For more information about NAT, see RFC 1631: The IP Network Address Translator (NAT).

**Note**

Instances that access other instances through their public NAT IP address are charged for regional or Internet data transfer, depending on whether the instances are in the same region.

Determining Your Public, Private, and Elastic IP Addresses

You can use the EC2 console to determine the private IP addresses, public IP addresses, and EIPs of your instances.

To determine your instance’s IP addresses using the console

1. Open the Amazon EC2 console.
2. Click Instances in the navigation pane.
3. Select an instance. The console displays information about the instance in the lower pane.
4. Get the public IP address from the Public IP field.
5. If an EIP has been associated with the instance, get the EIP from the Elastic IP field.
6. Get the private IP address from the Private IP field.

You can also determine the public and private IP addresses of your instances using instance metadata. For more information about instance metadata, see Instance Metadata and User Data (p. 268).

To determine your instance’s IP addresses using instance metadata

1. Connect to the instance.
2. Use the following command to access the private IP address:

3. Use the following command to access the public IP address:

   Note that if an EIP is associated with the instance, the value returned is that of the EIP.
Assigning a Public IP Address

If you launch an instance in EC2-Classic, it is assigned a public IP address by default. You can't modify this behavior.

If you launch an instance into a VPC, a public IP addressing feature is available for you to control whether your instance is assigned a public IP address. The public IP address is assigned from Amazon's pool of public IP addresses, and is assigned to the network interface with the device index of eth0. This feature depends on certain conditions at the time you launch your instance.

**Important**
You can't manually disassociate the public IP address from your instance after launch. Instead, it's automatically released in certain cases, after which you cannot reuse it. For more information, see Public IP Addresses and External DNS Hostnames (p. 490). If you require a persistent public IP address that you can associate or disassociate at will, assign an Elastic IP address to the instance after launch instead. For more information, see Elastic IP Addresses (EIP) (p. 498).

To access the public IP addressing feature when launching an instance

1. Open the Amazon EC2 console.
2. Click Launch Instance.
3. Choose an AMI and click its Select button, then choose an instance type and click Next: Configure Instance Details.
4. On the Configure Instance Details page, select a VPC from the Network list. A Public IP check box is displayed. Select the check box to assign a public IP address to your instance. If you select a default subnet, the Public IP check box is selected by default.

   The following rules apply:

   - A public IP address can only be assigned to a single network interface with the device index of eth0. The Public IP check box is not available if you're launching with multiple network interfaces, and is not available for the eth1 network interface.
   - You can only assign a public IP address to a new network interface, not an existing one.

5. Follow the steps on the next pages of the wizard to complete your instance's setup. For more information about the wizard configuration options, see Launching an Instance (p. 300). On the final Review Instance Launch page, review your settings, and then click Launch to choose a key pair and launch your instance.
6. On the Instances page, select your new instance and view its public IP address in Public IP field in the details pane.

The public IP addressing feature is only available during launch. However, whether you assign a public IP address to your instance during launch or not, you can associate an Elastic IP address with your instance after it's launched. For more information, see Elastic IP Addresses (EIP) (p. 498).

**API and Command Line Tools for Public IP Addressing**

To enable or disable the public IP addressing feature, use one of the methods in the table below. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

### Multiple Private IP Addresses

In EC2-VPC, you can specify multiple private IP addresses for your instances. The number of network interfaces and private IP addresses that you can specify for an instance depends on the instance type. For more information, see Private IP Addresses Per ENI Per Instance Type (p. 504).

It can be useful to assign multiple private IP addresses to an instance in your VPC to do the following:

- Host multiple websites on a single server by using multiple SSL certificates on a single server and associating each certificate with a specific IP address.
- Operate network appliances, such as firewalls or load balancers, that have multiple private IP addresses for each network interface.
- Redirect internal traffic to a standby instance in case your instance fails, by reassigning the secondary private IP address to the standby instance.

- Viewing Your Secondary Private IP Addresses (p. 497)
- Unassigning a Secondary Private IP Address (p. 498)

### How Multiple IP Addresses Work

The following list explains how multiple IP addresses work with network interfaces:

- You can assign a secondary private IP address to any network interface. The network interface can be attached to or detached from the instance.
- You must choose a secondary private IP address that's in the CIDR block range of the subnet for the network interface.
- Security groups apply to network interfaces, not to IP addresses. Therefore, IP addresses are subject to the security group of the network interface in which they're specified.
- Secondary private IP addresses can be assigned and unassigned to elastic network interfaces attached to running or stopped instances.
• Secondary private IP addresses that are assigned to a network interface can be reassigned to another one if you explicitly allow it.

• When assigning multiple secondary private IP addresses to a network interface using the command line tools or API, the entire operation fails if one of the secondary private IP addresses can't be assigned.

• Primary private IP addresses, secondary private IP addresses, and any associated Elastic IP addresses remain with the network interface when it is detached from an instance or attached to another instance.

• Although you can't move the primary network interface from an instance, you can reassign the secondary private IP address of the primary network interface to another network interface.

• You can move any additional network interface from one instance to another.

The following list explains how multiple IP addresses work with Elastic IP addresses:

• Each private IP address can be associated with a single Elastic IP address, and vice versa.

• When a secondary private IP address is reassigned to another interface, the secondary private IP address retains its association with an Elastic IP address.

• When a secondary private IP address is unassigned from an interface, an associated Elastic IP address is automatically disassociated from the secondary private IP address.

### Assigning a Secondary Private IP Address

You can assign the secondary private IP address to the network interface for an instance as you launch the instance, or after the instance is running.

#### To assign a secondary private IP address when launching an instance in EC2-VPC

1. Open the Amazon EC2 console.
2. Click the **Launch Instance** button.
3. Choose an AMI and click its **Select** button, then choose an instance type and click **Next: Configure Instance Details**.
4. On the **Configure Instance Details** page, choose a VPC from the **Network** list, and a subnet from the **Subnet** list.
5. In the **Network Interfaces** section, do the following, and then click **Next: Add Storage**:
   a. Click **Add Device** to add another network interface. The console enables you specify up to 2 network interfaces when you launch an instance. After you launch the instance, click **Network Interfaces** in the navigation pane to add additional network interfaces. The total number of network interfaces that you can attach varies by instance type. For more information, see [Private IP Addresses Per ENI Per Instance Type](p. 504).
   b. For each network interface, you can specify a primary private IP address, and one or more secondary private IP addresses. For this example, however, accept the IP address that we automatically assign.
   c. Under **Secondary IP addresses**, click **Add IP**, and then enter a private IP address in the subnet range, or accept the default, **Auto-assign**, to let us select an address.

   **Important**
   After you have added a secondary private IP address to a network interface, you must connect to the instance and configure the secondary private IP address on the instance itself. For more information, see [Configuring the Operating System on Your Instance to Recognize the Secondary Private IP Address](p. 497).

6. On the next **Add Storage** page, you can specify volumes to attach to the instance besides the volumes specified by the AMI (such as the root device volume), and then click **Next: Tag Instance**.
7. On the **Tag Instance** page, specify tags for the instance, such as a user-friendly name, and then click **Next: Configure Security Group**.

8. On the **Configure Security Group** page, select an existing security group or create a new one. Click **Review and Launch**.

9. On the **Review Instance Launch** page, review your settings, and then click **Launch** to choose a key pair and launch your instance. If you’re new to Amazon EC2 and haven’t created any key pairs, the wizard prompts you to create one.

### To assign a secondary IP address during launch using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- The **--secondary-private-ip-addresses** option with the **run-instances** command (AWS CLI)
- The **--secondary-private-ip-address** option with the **ec2-run-instances** command (Amazon EC2 CLI)

### To assign a secondary private IP to an existing instance

1. Open the Amazon EC2 console.
2. In the navigation pane, click **Network Interfaces**, and then right-click the network interface attached to the instance.
3. Select **Manage Private IP Addresses**.
4. In the **Manage Private IP Addresses** dialog box, do the following:
   a. Click **Assign new IP**.
   b. Enter a specific IP address that’s within the subnet range for the instance, or leave the field blank and we’ll select an IP address for you.
   c. (Optional) Select **Allow reassignment** to allow the secondary private IP address to be reassigned if it is already assigned to another network interface.
   d. Click **Yes, Update**, and then click **Close**.

#### Note
You can also assign a secondary private IP address to an instance by clicking **Instances** in the navigation pane, right-clicking your instance, and selecting **Manage Private IP Addresses**. You can configure the same information in the dialog as you did in the steps above.

### To assign a secondary private IP to an existing instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- **assign-private-ip-addresses** (AWS CLI)
- **ec2-assign-private-ip-addresses** (Amazon EC2 CLI)
- **Register-EC2PrivateIpAddress** (AWS Tools for Windows PowerShell)
Configuring the Operating System on Your Instance to Recognize the Secondary Private IP Address

After you assign a secondary private IP address to your instance, you need to configure the operating system on your instance to recognize the secondary private IP address.

If you are using Amazon Linux, the ec2-net-utils package can take care of this step for you. It configures additional network interfaces that you attach while the instance is running, refreshes secondary IP addresses during DHCP lease renewal, and updates the related routing rules. If you require manual control over your network configuration, you can remove the ec2-net-utils package. For more information, see Configuring Your Network Interface Using ec2-net-utils (p. 507).

If you are using another Linux distribution, see the documentation for your Linux distribution. Search for information about configuring additional network interfaces and secondary IP addresses. If the instance has two or more interfaces on the same subnet, search for information about using routing rules to work around asymmetric routing.

For information about configuring a Windows instance, see Configuring a Secondary Private IP Address for Your Windows Instance in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

Associating an Elastic IP Address with the Secondary Private IP Address

To associate an EIP with a secondary private IP address in EC2-VPC

1. Open the Amazon EC2 console.
2. Click Elastic IPs in the navigation pane.
3. Right-click the IP address, and then click Associate.
4. In the Associate Address dialog box, select the network interface from the Network Interface drop-down list, and then select the secondary IP address from the Private IP address drop-down list.
5. Click Associate.

To associate an EIP with a secondary private IP address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- associate-address (AWS CLI)
- ec2-associate-address (Amazon EC2 CLI)
- Register-EC2Address (AWS Tools for Windows PowerShell)

Viewing Your Secondary Private IP Addresses

To view the private IP addresses assigned to a network interface in EC2-VPC

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select the network interface whose private IP addresses you want to view.
4. On the Details tab in the details pane, check the Primary private IP and Secondary private IPs fields for the primary private IP address and any secondary private IP addresses assigned to the network interface.
To view the private IP addresses assigned to an instance
1. Open the Amazon EC2 console.
2. Click **Instances** in the navigation pane.
3. Select the instance whose private IP addresses you want to view.
4. On the **Description** tab in the details pane, check the **Private IPs** and **Secondary private IPs** fields for the primary private IP address and any secondary private IP addresses assigned to the instance through its network interface.

Unassigning a Secondary Private IP Address
If you no longer require a secondary private IP address, you can unassign it from the instance or the network interface. When a secondary private IP address is unassigned from an elastic network interface, the Elastic IP address (if it exists) is also disassociated.

To unassign a secondary private IP address from an instance
1. Open the Amazon EC2 console.
2. Click **Instances** in the navigation pane.
3. Right-click an instance, and then click **Manage Private IP Addresses**.
4. In the **Manage Private IP Addresses** dialog box, beside the secondary private IP address to unassign, click **Unassign**.
5. Click **Yes, Update**, and then close the dialog box.

To unassign a secondary private IP address from a network interface
1. Open the Amazon EC2 console.
2. Click **Network Interface** in the navigation pane.
3. Right-click an instance, and the click **Manage Private IP Addresses**.
4. In the **Manage Private IP Addresses** dialog box, beside the secondary private IP address to unassign, click **Unassign**.
5. Click **Yes, Update**, and then click **Close**.

To unassign a secondary private IP address using the command line
You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `unassign-private-ip-addresses` (AWS CLI)
- `ec2-unassign-private-ip-addresses` (Amazon EC2 CLI)
- `Unregister-EC2PrivateIpAddress` (AWS Tools for Windows PowerShell)

Elastic IP Addresses (EIP)

An **Elastic IP address** (EIP) is a static IP address designed for dynamic cloud computing. With an EIP, you can mask the failure of an instance or software by rapidly remapping the address to another instance in your account. Your EIP is associated with your AWS account, not a particular instance, and it remains associated with your account until you choose to explicitly release it.
There's one pool of EIPs for use with the EC2-Classic platform and another for use with your VPC. You can't associate an EIP that you allocated for use with a VPC with an instance in EC2-Classic, and vice-versa. For more information about EC2-Classic and EC2-VPC, see Supported Platforms (p. 487).

**Elastic IP Addresses in EC2-Classic**

By default, we assign each instance in EC2-Classic two IP addresses at launch: a private IP address and a public IP address that is mapped to the private IP address through network address translation (NAT). The public IP address is allocated from the EC2-Classic public IP address pool, and is associated with your instance, not with your AWS account. You cannot reuse a public IP address after it's been disassociated from your instance.

If you use dynamic DNS to map an existing DNS name to a new instance's public IP address, it might take up to 24 hours for the IP address to propagate through the Internet. As a result, new instances might not receive traffic while terminated instances continue to receive requests. To solve this problem, use an EIP.

When you associate an EIP with an instance, the instance's current public IP address is released to the EC2-Classic public IP address pool. If you disassociate an EIP from the instance, the instance is automatically assigned a new public IP address within a few minutes. In addition, stopping the instance also disassociates the EIP from it.

To ensure efficient use of EIPs, we impose a small hourly charge if an EIP is not associated with a running instance. For more information, see Amazon EC2 Pricing.

**Elastic IP Addresses in a VPC**

We assign each instance in a default VPC two IP addresses at launch: a private IP address and a public IP address that is mapped to the private IP address through network address translation (NAT). The public IP address is allocated from the EC2-VPC public IP address pool, and is associated with your instance, not with your AWS account. You cannot reuse a public IP address after it's been disassociated from your instance.

We assign each instance in a nondefault VPC only a private IP address, unless you specifically request a public IP address during launch. To ensure that an instance in a nondefault VPC that has not been assigned a public IP address can communicate with the Internet, you must allocate an Elastic IP address for use with a VPC, and then associate that EIP with the elastic network interface (ENI) attached to the instance.

When you associate an EIP with an instance in a default VPC, or an instance in which you assigned a public IP to the eth0 network interface during launch, its current public IP address is released to the EC2-VPC public IP address pool. If you disassociate an EIP from the instance, the instance is automatically
assigned a new public IP address within a few minutes. However, if you have attached a second network interface to the instance, the instance is not automatically assigned a new public IP address; you'll have to associate an EIP with it manually. The EIP remains associated with the instance when you stop it.

To ensure efficient use of EIPs, we impose a small hourly charge if an EIP is not associated with a running instance, or if it is associated with a stopped instance or an unattached network interface. While your instance is running, you are not charged for one EIP associated with the instance, but you are charged for any additional EIPs associated with the instance. For more information, see Amazon EC2 Pricing.

For information about using an EIP with an instance in a VPC, see Elastic IP Addresses in the Amazon Virtual Private Cloud User Guide.

Differences Between EC2-Classic and EC2-VPC

The following table lists the differences between EIPs on EC2-Classic and EC2-VPC.

Allocating an Elastic IP Address

You can allocate an Elastic IP address using the AWS Management Console or the command line.

To allocate an Elastic IP address for use with EC2-Classic using the console

1. Open the Amazon EC2 console.
2. Click Elastic IPs in the navigation pane.
3. Click Allocate New Address.
4. Select EC2 from the EIP list, and then click Yes, Allocate. Close the confirmation dialog box.
To allocate an Elastic IP address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `allocate-address` (AWS CLI)
- `ec2-allocate-address` (Amazon EC2 CLI)
- `New-EC2Address` (AWS Tools for Windows PowerShell)

### Describing Your Elastic IP Addresses

You can describe an Elastic IP address using the AWS Management Console or the command line.

**To describe your Elastic IP addresses using the console**

1. Open the Amazon EC2 console.
2. Click Elastic IPs in the navigation pane.
3. To filter the displayed list, start typing part of the EIP or the ID of the instance to which it is assigned in the search box.

**To describe your Elastic IP addresses using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-addresses` (AWS CLI)
- `ec2-describe-addresses` (Amazon EC2 CLI)
- `Get-EC2Address` (AWS Tools for Windows PowerShell)

### Associating an Elastic IP Address with a Running Instance

You can associate an Elastic IP address to an instance using the AWS Management Console or the command line.

**To associate an Elastic IP address with an instance using the console**

1. Open the Amazon EC2 console.
2. Click Elastic IPs in the navigation pane.
3. Select an EIP and click Associate Address.
4. In the Associate Address dialog box, select the instance from the Instance list box and click Associate.

**To associate an Elastic IP address using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `associate-address` (AWS CLI)
- `ec2-associate-address` (Amazon EC2 CLI)
- `Register-EC2Address` (AWS Tools for Windows PowerShell)
Associating an Elastic IP Address with a Different Running Instance

You can reassociate an Elastic IP address using the AWS Management Console or the command line.

To reassociate an Elastic IP address using the console

1. Open the Amazon EC2 console.
2. Click Elastic IPs in the navigation pane.
3. Select the EIP, and then click the Disassociate button.
4. Click Yes, Disassociate when prompted.
5. Select the EIP, and then click Associate.
6. In the Associate Address dialog box, select the new instance from the Instance list, and then click Associate.

To disassociate an Elastic IP address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- disassociate-address (AWS CLI)
- ec2-disassociate-address (Amazon EC2 CLI)
- Unregister-EC2Address (AWS Tools for Windows PowerShell)

To associate an Elastic IP address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- associate-address (AWS CLI)
- ec2-associate-address (Amazon EC2 CLI)
- Register-EC2Address (AWS Tools for Windows PowerShell)

Releasing an Elastic IP Address

If you no longer need an EIP, we recommend that you release it (the address must not be associated with an instance). You incur charges for any EIP that's allocated for use with EC2-Classic but not associated with an instance.

You can release an Elastic IP address using the AWS Management Console or the command line.

To release an Elastic IP address using the console

1. Open the Amazon EC2 console.
2. Click Elastic IPs in the navigation pane.
3. Select the Elastic IP address, click the Release Address button, and then click Yes, Release when prompted.
To release an Elastic IP address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `release-address` (AWS CLI)
- `ec2-release-address` (Amazon EC2 CLI)
- `Remove-EC2Address` (AWS Tools for Windows PowerShell)

Using Reverse DNS for Email Applications

If you intend to send email to third parties from an instance, we suggest you provision one or more Elastic IP addresses and provide them to us in the Request to Remove Email Sending Limitations form. AWS works with ISPs and Internet anti-spam organizations (such as Spamhaus) to reduce the chance that your email sent from these addresses will be flagged as spam.

In addition, assigning a static reverse DNS record to your Elastic IP address used to send email can help avoid having email flagged as spam by some anti-spam organizations. You can provide us with a reverse DNS record to associate with your addresses through the aforementioned form. Note that a corresponding forward DNS record (A Record) pointing to your Elastic IP address must exist before we can create your reverse DNS record.

Elastic IP Address Limit

By default, all AWS accounts are limited to 5 EIPs, because public (IPv4) Internet addresses are a scarce public resource. We strongly encourage you to use an EIP primarily for load balancing use cases, and use DNS hostnames for all other inter-node communication.

If you feel your architecture warrants additional EIPs, please complete the Amazon EC2 Elastic IP Address Request Form. We will ask you to describe your use case so that we can understand your need for additional addresses.

Elastic Network Interfaces (ENI)

An elastic network interface (ENI) is a virtual network interface that you can attach to an instance in a VPC. An ENI can include the following attributes:

- a primary private IP address
- one or more secondary private IP addresses
- one Elastic IP address per private IP address
- one public IP address, which can be auto-assigned to the network interface for eth0 when you launch an instance, but only when you create a network interface for eth0 instead of using an existing network interface
- one or more security groups
- a MAC address
- a source/destination check flag
- a description

You can create a network interface, attach it to an instance, detach it from an instance, and attach it to another instance. The attributes of a network interface follow the network interface as it is attached or...
detached from an instance and reattached to another instance. When you move a network interface from
one instance to another, network traffic is redirected to the new instance.

Each instance in a VPC has a default network interface. The default network interface has a primary
private IP address in the IP address range of its VPC. You can create and attach additional network
interfaces. The maximum number of network interfaces that you can use varies by instance type. For
more information, see Private IP Addresses Per ENI Per Instance Type (p. 504).

Attaching multiple network interfaces to an instance is useful when you want to:

• Create a management network.
• Use network and security appliances in your VPC.
• Create dual-homed instances with workloads/roles on distinct subnets.
• Create a low-budget, high-availability solution.

Private IP Addresses Per ENI Per Instance Type

The following table lists the maximum number of elastic network interfaces (ENI) per instance type, and
the maximum number of private IP addresses per ENI. ENIs and multiple private IP addresses are only
available for instances running in a VPC. For more information, see Multiple Private IP Addresses (p. 494).

Creating a Management Network

You can create a management network using network interfaces. In this scenario, the secondary network interface on the instance handles public-facing traffic and the primary network interface handles back-end management traffic and is connected to a separate subnet in your VPC that has more restrictive access controls. The public facing interface, which may or may not be behind a load balancer, has an associated security group that allows access to the server from the Internet (for example, allow TCP port 80 and 443 from 0.0.0.0/0, or from the load balancer) while the private facing interface has an associated security group allowing SSH access only from an allowed range of IP addresses either within the VPC or from the Internet, a private subnet within the VPC or a virtual private gateway.

To ensure failover capabilities, consider using a secondary private IP for incoming traffic on a network interface. In the event of an instance failure, you can move the interface and/or secondary private IP address to a standby instance.

Use Network and Security Appliances in Your VPC

Some network and security appliances, such as load balancers, network address translation (NAT) servers, and proxy servers prefer to be configured with multiple network interfaces. You can create and attach secondary network interfaces to instances in a VPC that are running these types of applications and configure the additional interfaces with their own public and private IP addresses, security groups, and source/destination checking.

Creating Dual-homed Instances with Workloads/Roles on Distinct Subnets

You can place a network interface on each of your web servers that connects to a mid-tier network where an application server resides. The application server can also be dual-homed to a back-end network (subnet) where the database server resides. Instead of routing network packets through the dual-homed instances, each dual-homed instance receives and processes requests on the front end, initiates a connection to the back end, and then sends requests to the servers on the back-end network.
Create a Low Budget High Availability Solution

If one of your instances serving a particular function fails, its network interface can be attached to a replacement or hot standby instance pre-configured for the same role in order to rapidly recover the service. For example, you can use an ENI as your primary or secondary network interface to a critical service such as a database instance or a NAT instance. If the instance fails, you (or more likely, the code running on your behalf) can attach the ENI to a hot standby instance. Because the interface maintains its private IP addresses, Elastic IP addresses, and MAC address, network traffic will begin flowing to the standby instance as soon as you attach the ENI to the replacement instance. Users will experience a brief loss of connectivity between the time the instance fails and the time that the ENI is attached to the standby instance, but no changes to the VPC route table or your DNS server are required.

Best Practices for Configuring Network Interfaces

- You can attach a network interface to an instance when it's running (hot attach), when it's stopped (warm attach), or when the instance is being launched (cold attach).
- You can detach secondary (ethN) network interfaces when the instance is running or stopped. However, you can't detach the primary (eth0) interface.
- You can attach a network interface in one subnet to an instance in another subnet in the same VPC, however, both the network interface and the instance must reside in the same Availability Zone.
- When launching an instance from the CLI or API, you can specify the network interfaces to attach to the instance for both the primary (eth0) and additional network interfaces.
- Launching an instance with multiple network interfaces automatically configures interfaces, private IP addresses, and route tables on the operating system of the instance. A warm or hot attach of an additional network interface may require you to manually bring up the second interface, configure the private IP address, and modify the route table accordingly. (Instances running Microsoft Windows Server or Amazon Linux automatically recognize the warm or hot attach and configure themselves.)
- Attaching another network interface to an instance is not a method to increase or double the network bandwidth to or from the dual-homed instance.

Configuring Your Network Interface Using ec2-net-utils

Amazon Linux AMIs may contain additional scripts installed by Amazon Web Services, known as ec2-net-utils. These scripts optionally automate the configuration of your elastic network interfaces (ENIs).

Use the following command to install the package on Amazon Linux if it's not already installed, or update it if it's installed and additional updates are available:

```
yum install ec2-net-utils
```

The following components are part of ec2-net-utils:

- **udev rules (/etc/udev/rules.d)**
  Identifies network interfaces when they are attached, detached, or reattached to a running instance, and ensures that the hotplug script runs (53-ec2-network-interfaces.rules). Maps the MAC address to a device name (75-persistent-net-generator.rules, which generates 70-persistent-net.rules).

- **hotplug script**
DHCP script
Whenever the network interface receives a new DHCP lease, this script queries the instance metadata for Elastic IP addresses. For each Elastic IP address, it adds a rule to the routing policy database to ensure that outbound traffic from that address uses the correct network interface. It also adds each private IP address to the network interface as a secondary address.

`ec2ifup ethN`  
Extends the functionality of the standard `ifup`. After this script rewrites the configuration files `ifcfg-ethN` and `route-ethN`, it runs `ifup`.

`ec2ifdown ethN`  
Extends the functionality of the standard `ifdown`. After this script removes any rules for the network interface from the routing policy database, it runs `ifdown`.

`ec2ifscan`  
Checks for network interfaces that have not been configured and configures them.

Note that this script isn't available in the initial release of ec2-net-utils.

To list any configuration files that were generated by ec2-net-utils, use the following command:

```
ls -l /etc/sysconfig/network-scripts/*-eth?
```

To disable the automation on a per-instance basis, you can add `EC2SYNC=no` to the corresponding `ifcfg-ethN` file. For example, use the following command to disable the automation for the eth1 interface:

```
sed -i -e 's/^EC2SYNC=yes/EC2SYNC=no/' /etc/sysconfig/network-scripts/ifcfg-eth1
```

If you want to disable the automation completely, you can remove the package using the following command:

```
yum remove ec2-net-utils
```

### Creating a Network Interface

You can create a network interface using the AWS Management Console or the command line.

**To create a network interface using the console**

1. Open the Amazon EC2 console.
2. Click **Network Interfaces** in the navigation pane.
3. Click **Create Network Interface**.
4. In the **Create Network Interface** dialog box, provide the following information for the network interface, and then click **Yes, Create**.
   a. In **Description**, enter a descriptive name.
   b. In **Subnet**, select the subnet. Note that you can't move the network interface to another subnet after it's created, and you can only attach the network interface to instances in the same subnet.
   c. In **Private IP**, enter the primary private IP address. If you don't specify an IP address, we'll select an available private IP address from within the selected subnet.
   d. In **Security groups**, select one or more security groups.
To create a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `create-network-interface` (AWS CLI)
- `ec2-create-network-interface` (Amazon EC2 CLI)
- `New-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

Deleting a Network Interface

You must first detach a network interface from an instance before you can delete it. Deleting a network interface releases all attributes associated with the network interface and releases any private IP addresses or Elastic IP addresses to be used by another instance.

You can delete a network interface using the AWS Management Console or the command line.

To delete a network interface using the console

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select a network interface, and then click the Delete button.
4. In the Delete Network Interface dialog box, click Yes, Delete.

To delete a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `delete-network-interface` (AWS CLI)
- `ec2-delete-network-interface` (Amazon EC2 CLI)
- `Remove-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

Viewing Details about a Network Interface

You can describe a network interface using the AWS Management Console or the command line.

To describe a network interface using the console

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select the network interface.
4. View the details on the Details tab.

To describe a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-network-interfaces` (AWS CLI)
- `ec2-describe-network-interfaces` (Amazon EC2 CLI)
- `Get-EC2NetworkInterface` (AWS Tools for Windows PowerShell)
To describe a network interface attribute using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- describe-network-interface-attribute (AWS CLI)
- ec2-describe-network-interface-attribute (Amazon EC2 CLI)

Attaching a Network Interface When Launching an Instance

You can attach an additional network interface to an instance when you launch it into a VPC.

Note

If an error occurs when attaching a network interface to your instance, this causes the instance launch to fail.

You can attach a network interface to an instance using the AWS Management Console or the command line.

To attach a network interface when launching an instance using the console

1. Open the Amazon EC2 console.
2. Click Launch Instance.
3. Choose an AMI and click its Select button, then choose an instance type and click Next: Configure Instance Details.
4. On the Configure Instance Details page, select a VPC from the Network list, and a subnet from the Subnet list.

To assign a public IP address to your instance, select the Automatically assign a public IP address to your instances check box. If you selected a default subnet, this check box is selected by default. Note that you can't assign a public IP address to your instance if you specify an existing network interface for the primary network interface (eth0) or multiple network interfaces in the next step.

5. In the Network Interfaces section, the console enables you specify up to 2 network interfaces (new, existing, or a combination) when you launch an instance. You can also enter a primary IP address and one or more secondary IP addresses for any new network interface. When you've finished, click Next: Add Storage.

Note that you can add additional network interfaces to the instance after you launch it. The total number of network interfaces that you can attach varies by instance type. For more information, see Private IP Addresses Per ENI Per Instance Type (p. 504).

6. On the next Add Storage page, you can specify volumes to attach to the instance besides the volumes specified by the AMI (such as the root device volume), and then click Next: Tag Instance.
7. On the Tag Instance page, specify tags for the instance, such as a user-friendly name, and then click Next: Configure Security Group.
8. On the Configure Security Group page, select an existing security group or create a new one. Click Review and Launch.
9. On the Review Instance Launch page, details about the primary and additional network interface are displayed. Review the settings, and then click Launch to choose a key pair and launch your instance. If you're new to Amazon EC2 and haven't created any key pairs, the wizard prompts you to create one.
To attach a network interface when launching an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- run-instances (AWS CLI)
- ec2-run-instances (Amazon EC2 CLI)
- New-EC2Instance (AWS Tools for Windows PowerShell)

Attaching a Network Interface to a Stopped or Running Instance

You can attach a network interface to any of your stopped or running instances in your VPC using either the Instances or Network Interfaces page of the Amazon EC2 console, or using a command line interface.

To attach a network interface to an instance using the Instances page

1. Open the Amazon EC2 console.
2. Click Instances in the navigation pane.
3. Right-click the instance, and then select Attach Network Interface.
4. In the Attach Network Interface dialog box, select the network interface, and then click Attach.

To attach a network interface to an instance using the Network Interfaces page

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select the network interface.
4. Click the Attach button.
5. In the Attach Network Interface dialog box, select the instance, and then click Attach.

To attach a network interface to an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- attach-network-interface (AWS CLI)
- ec2-attach-network-interface (Amazon EC2 CLI)
- Add-EC2NetworkInterface (AWS Tools for Windows PowerShell)

Detaching a Network Interface from an Instance

You can detach an secondary network interface at any time, using either the Instances or Network Interfaces page of the Amazon EC2 console, or using a command line interface.

To detach a network interface from an instance using the Instances page

1. Open the Amazon EC2 console.
2. Click Instances in the navigation pane.
3. Right-click the instance, and then select Detach Network Interface.
4. In the Detach Network Interface dialog box, select the network interface, and then click Detach.
To detach a network interface from an instance using the Network Interfaces page

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select the network interface, and then click the Detach button.
4. In the Detach Network Interface dialog box, click Yes, Detach. If the network interface fails to detach from the instance, select Force detachment, and then try again.

To detach a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- detach-network-interface (AWS CLI)
- ec2-detach-network-interface (Amazon EC2 CLI)
- Dismount-EC2NetworkInterface (AWS Tools for Windows PowerShell)

Changing the Security Group of a Network Interface

You can change the security groups that are associated with a network interface. When you create the security group, be sure to specify the same VPC as the subnet for the network interface.

You can change the security group for your network interfaces using the AWS Management Console or the command line.

Note
To change security group membership for interfaces owned by other Amazon Web Services, such as Elastic Load Balancing, use the console or command line interface for that service.

To change the security group of a network interface using the console

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select the network interface.
4. Right-click the network interface, and then select Change Security Groups.
5. In the Change Security Groups dialog box, select the security groups to use, and then click Save.

To change the security group of a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- modify-network-interface-attribute (AWS CLI)
- ec2-modify-network-interface-attribute (Amazon EC2 CLI)
- Edit-EC2NetworkInterfaceAttribute (AWS Tools for Windows PowerShell)
Changing the Source/Destination Checking of a Network Interface

The Source/Destination Check attribute controls whether source/destination checking is enabled on the instance. Disabling this attribute enables an instance to handle network traffic that isn't specifically destined for the instance. For example, instances running services such as network address translation, routing, or a firewall should set this value to disabled. The default value is enabled.

You can change source/destination checking using the AWS Management Console or the command line.

To change source/destination checking for a network interface using the console

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Right-click the network interface, and then select Change Source/Dest Check.
4. In the dialog box, select Enabled (if enabling), or Disabled (if disabling), and then click Save.

To change source/destination checking for a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- modify-network-interface-attribute (AWS CLI)
- ec2-modify-network-interface-attribute (Amazon EC2 CLI)
- Edit-EC2NetworkInterfaceAttribute (AWS Tools for Windows PowerShell)

Associating an Elastic IP Address with a Network Interface

If you have an Elastic IP address, you can associate it with one of the private IP addresses for the network interface. You can associate one Elastic IP address with each private IP address.

You can associate an Elastic IP address using the AWS Management Console or the command line.

To associate an Elastic IP address using the console

1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Right-click the network interface, and then select Associate Address.
4. In the Associate Elastic IP Address dialog box, select the Elastic IP address from the Address list.
5. In Associate to private IP address, select the private IP address to associate with the Elastic IP address.
6. Select Allow reassociation to allow the Elastic IP address to be associated with the specified network interface if it's currently associated with another instance or network interface, and then click Associate Address.

To associate an Elastic IP address using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).
Disassociating an Elastic IP Address from a Network Interface

If the network interface has an Elastic IP address associated with it, you can disassociate the address, and then either associate it with another network interface or release it back to the address pool. Note that this is the only way to associate an Elastic IP address with an instance in a different subnet or VPC using a network interface, as network interfaces are specific to a particular subnet.

You can disassociate an Elastic IP address using the AWS Management Console or the command line.

To disassociate an Elastic IP address using the console
1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Right-click the network interface, and then select Disassociate Address.
4. In the Disassociate IP Address dialog box, click Yes, Disassociate.

To disassociate an Elastic IP address using the command line
You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

• disassociate-address (AWS CLI)
• ec2-disassociate-address (Amazon EC2 CLI)
• Unregister-EC2Address (AWS Tools for Windows PowerShell)

Changing Termination Behavior for a Network Interface

You can set the termination behavior for a network interface attached to an instance so that it is automatically deleted when you delete the instance it's attached to.

Note
By default, network interfaces that are automatically created and attached to instances using the AWS Management Console are set to terminate when the instance terminates. However, network interfaces created using the command line interface aren't set to terminate when the instance terminates.

You can change the terminating behavior for a network interface using the AWS Management Console or the command line.

To change the termination behavior for a network interface using the console
1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Right-click the network interface, and then select Change Termination Behavior.
4. In the Change Termination Behavior dialog box, select the Delete on termination check box if you want the network interface to be deleted when you terminate an instance.

To change the termination behavior for a network interface using the command line
You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- modify-network-interface-attribute (AWS CLI)
- ec2-modify-network-interface-attribute (Amazon EC2 CLI)
- Edit-EC2NetworkInterfaceAttribute (AWS Tools for Windows PowerShell)

Adding or Editing a Description for a Network Interface
You can change the description for a network interface using the AWS Management Console or the command line.

To change the description for a network interface using the console
1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Right-click the network interface, and then select Change Description.
4. In the Change Description dialog box, enter a description for the network interface, and then click Save.

To change the description for a network interface using the command line
You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- modify-network-interface-attribute (AWS CLI)
- ec2-modify-network-interface-attribute (Amazon EC2 CLI)
- Edit-EC2NetworkInterfaceAttribute (AWS Tools for Windows PowerShell)

Adding or Editing Tags for a Network Interface
Tags are metadata that you can add to a network interface. Tags are private and are only visible to your account. Each tag consists of a key and an optional value. For more information about tags, see Tagging Your Amazon EC2 Resources (p. 610).

You can tag a resource using the AWS Management Console or the command line.

To add or edit tags for a network interface using the console
1. Open the Amazon EC2 console.
2. Click Network Interfaces in the navigation pane.
3. Select the network interface.
4. In the details pane, click the Tags tab, and then click Add/Edit Tags.
5. In the Add/Edit Tags dialog, click Create Tag for each tag you want to create, and enter a key and optional value. When you’re done, click Save.
To add or edit tags for a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `create-tags` (AWS CLI)
- `ec2-create-tags` (Amazon EC2 CLI)
- `New-EC2Tag` (AWS Tools for Windows PowerShell)

Enabling Enhanced Networking on Linux Instances in a VPC

With C3, R3, and I2 instances, you can enable enhanced networking capabilities. We support enhanced networking capabilities using single root I/O virtualization (SR-IOV). Enabling enhanced networking on your instance results in higher performance (packets per second), lower latency, and lower jitter.

To enable enhanced networking on your instance, you must ensure that its kernel has the required driver installed, and that you set the `sriovNetSupport` attribute for the instance.

Topics

- Requirements (p. 516)
- Using Amazon Linux (p. 516)
- Using Linux Distributions Other Than Amazon Linux (p. 518)
- Testing Whether Enhanced Networking Is Enabled (p. 519)

Note that you can get directions for Windows from Enabling Enhanced Networking on Windows Instances in a VPC in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

Requirements

- Launch the instance from an HVM AMI with a minimum Linux kernel version of 2.6.32.
- Launch the instance in a VPC.
- Install either the AWS CLI or Amazon EC2 CLI tools. For more information, see Accessing Amazon EC2 (p. 3).

If you choose the Amazon EC2 CLI tools, install version 1.6.12.0 or later. You can use the `ec2-version` command to verify the version of your CLI tools.

Using Amazon Linux

The latest Amazon Linux HVM AMIs have the driver required for enhanced networking installed and have the required attribute set. Therefore, if you launch an Amazon EBS–backed C3, R3, or I2 instance using a current Amazon Linux HVM AMI, enhanced networking is enabled for your instance. For more information, see Testing Whether Enhanced Networking Is Enabled (p. 519).

If you launch your instance using an older Amazon Linux AMI, use the following procedure to enable enhanced networking on an Amazon EBS-backed instance.

To enable enhanced networking on older versions of Amazon Linux

1. Connect to your instance.
2. From the instance, run the following command:

```bash
sudo yum update
```

3. From your computer, reboot your instance using the Amazon EC2 console or one of the following commands: `reboot-instances` (AWS CLI) or `ec2-reboot-instances` (Amazon EC2 CLI).

4. From your computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI) or `ec2-stop-instances` (Amazon EC2 CLI).

5. From your computer, enable the enhanced networking attribute using one of the following commands. Note that there is no way to disable the networking attribute after you've enabled it.

   **Warning**
   Enhanced networking is supported only for HVM instances. Enabling enhanced networking with a PV instance can make it unreachable.

   - `modify-instance-attribute` (AWS CLI)
     ```bash
     aws ec2 modify-instance-attribute --instance-id instance_id --sriov-net-support Value=simple
     ```
   - `ec2-modify-instance-attribute` (Amazon EC2 CLI)
     ```bash
     ec2-modify-instance-attribute instance_id --sriov simple
     ```

6. (Optional) Create an AMI from the instance, as described in Creating an Amazon EBS-Backed Linux AMI (p. 69). The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch a C3, R3, or I2 instance with the enhanced networking enabled by default.

7. From your computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI) or `ec2-start-instances` (Amazon EC2 CLI).

**Instance Store-Backed Instances**

If your instance is an instance store–backed instance, you can't stop the instance, modify its attributes, and create an image as described in the previous procedure. Instead, create a new AMI as described in Creating an Instance Store-Backed Linux AMI (p. 72). Be sure to enable the enhanced networking attribute when you register the AMI.

- `register-image` (AWS CLI)
  ```bash
  aws ec2 register-image --sriov-net-support Value=simple ...
  ```
- `ec2-register` (Amazon EC2 CLI)
  ```bash
  ec2-register --sriov simple ...
  ```
Using Linux Distributions Other Than Amazon Linux

The following procedure provides the general steps that you’ll take when enabling enhanced networking on a Linux distribution other than Amazon Linux. For more information, such as detailed syntax for commands, see the documentation for your Linux distribution.

To enable enhanced networking on Linux

1. Connect to your instance.
2. Ensure that the PCI Hot Plug capability is enabled on your instance.
3. Download and extract the source for the ixgbevf driver on your instance. Be sure to install a driver that is compatible with the kernel for your instance.
4. Compile and install the ixgbevf driver on your instance.
5. For the best performance, enable dynamic interrupt throttling for the installed driver as follows:

   ```
   echo "options ixgbevf InterruptThrottleRate=1,1,1,1,1,1,1,1" > /etc/modprobe.d/ixgbevf.conf
   ```

   Note that this is the typical location for `ixgbevf.conf`, but your Linux distribution might differ.
6. From your computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI) or `ec2-stop-instances` (Amazon EC2 CLI).
7. From your computer, enable the enhanced networking attribute using one of the following commands. Note that there is no way to disable the networking attribute after you've enabled it.

   **Warning**
   Enhanced networking is supported only for HVM instances. Enabling enhanced networking with a PV instance can make it unreachable.

   - `modify-instance-attribute` (AWS CLI)
     ```
     aws ec2 modify-instance-attribute --instance-id instance_id --sriov-net-support Value=simple
     ```
   - `ec2-modify-instance-attribute` (Amazon EC2 CLI)
     ```
     ec2-modify-instance-attribute instance_id --sriov simple
     ```

8. (Optional) Create an AMI from the instance, as described in Creating an Amazon EBS-Backed Linux AMI (p. 69). The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch a C3, R3, or I2 instance with the enhanced networking enabled by default.
9. From your computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI) or `ec2-start-instances` (Amazon EC2 CLI).
10. (Optional) Connect to your instance and verify that the driver is installed.

Instance Store–Backed Instances

If your instance is an instance store–backed instance, you can't stop the instance, modify its attributes, and create an image as described in the previous procedure. Instead, create a new AMI as described in
Creating an Instance Store-Backed Linux AMI (p. 72). Be sure to enable the enhanced networking attribute when you register the AMI.

**Warning**

This option is supported only for HVM AMIs. Specifying this option with a PV AMI can make instances launched from the AMI unreachable.

- **register-image** (AWS CLI)

  ```bash
  $ aws ec2 register-image --sriov-net-support Value=simple ...
  ```

- **ec2-register** (Amazon EC2 CLI)

  ```bash
  $ ec2-register --sriov simple ...
  ```

**Troubleshooting Connectivity Issues**

If you lose connectivity while enabling enhanced networking, the ixgbevf module might be incompatible with the kernel. Try installing the version of the ixgbevf module included with the distribution of Linux for your instance.

If you enable enhanced networking for a PV instance or AMI, this can make your instance unreachable.

**Testing Whether Enhanced Networking Is Enabled**

To test whether enhanced networking is enabled, verify that the driver is installed on your instance and that the `sriovNetSupport` attribute is set.

**Driver (ixgbevf)**

To verify that the ixgbevf driver is installed, use the `ethtool` command as follows:

```bash
$ sudo ethtool -i eth0
driver: ixgbevf
version: 2.11.3
firmware-version: N/A
bus-info: 0000:00:03.0
supports-statistics: yes
supports-test: yes
supports-eeprom-access: no
supports-register-dump: yes
supports-priv-flags: no
```

**Attribute (sriovNetSupport)**

To check whether an instance has the enhanced networking attribute set, use one of the following commands.

- **describe-instance-attribute** (AWS CLI)

  ```bash
  $ aws ec2 describe-instance-attribute --instance-id instance_id --attribute sriovNetSupport
  ```
If the enhanced networking attribute isn't set, SriovNetSupport is empty. Otherwise, SriovNetSupport is set as follows:

```
"SriovNetSupport": {
  "Value": "simple"
},
```

- **ec2-describe-instance-attribute** (Amazon EC2 CLI)

```
$ ec2-describe-instance-attribute instance_id --sriov
```

If the enhanced networking attribute isn't set, you'll see no output for this command. Otherwise, you'll see the following output.

```
sriovNetSupport instance_id simple
```

To check whether an AMI already has the enhanced networking attribute set, use one of the following commands.

- **describe-image-attribute** (AWS CLI)

```
$ aws ec2 describe-image-attribute --image-id ami_id --attribute sriovNetSupport
```

If the enhanced networking attribute isn't set, SriovNetSupport is empty. Otherwise, SriovNetSupport is set as follows:

```
"SriovNetSupport": {
  "Value": "simple"
},
```

- **ec2-describe-image-attribute** (Amazon EC2 CLI)

```
$ ec2-describe-image-attribute ami_id --sriov
```

If the enhanced networking attribute isn't set, you'll see no output for this command. Otherwise, you'll see the following output.

```
sriovNetSupport ami_id simple
```

Amazon EC2 provides you with flexible, cost effective, and easy-to-use data storage options for your instances. Each option has a unique combination of performance and durability. These storage options can be used independently or in combination to suit your requirements.

After reading this section, you should have a good understanding about how you can use the data storage options supported by Amazon Elastic Compute Cloud to meet your specific requirements. These storage options include the following:

- Amazon Elastic Block Store (Amazon EBS)
- Amazon EC2 instance store
- Amazon Simple Storage Service (Amazon S3)

The following figure shows the relationship between these types of storage.
Amazon EBS

Amazon EBS provides durable, block-level storage volumes that you can attach to a running Amazon EC2 instance. You can use Amazon EBS as a primary storage device for data that requires frequent and granular updates. For example, Amazon EBS is the recommended storage option when you run a database on an instance.

An Amazon EBS volume behaves like a raw, unformatted, external block device that you can attach to a single instance. The volume persists independently from the running life of an Amazon EC2 instance. After an EBS volume is attached to an instance, you can use it like any other physical hard drive. As illustrated in the previous figure, multiple volumes can be attached to an instance. You can also detach an EBS volume from one instance and attach it to another instance.

To keep a backup copy of your data, you can create a snapshot of an EBS volume, which is stored in Amazon S3. You can create a new Amazon EBS volume from a snapshot, and attach it to another instance. For more information, see Amazon Elastic Block Store (Amazon EBS) (p. 523).

Amazon EC2 Instance Store

Many Amazon EC2 instances can access storage from disks that are physically attached to the host computer. This disk storage is referred to as instance store. Instance store provides temporary block-level storage for Amazon EC2 instances. The data on an instance store volume persists only during the life of the associated Amazon EC2 instance; if you stop or terminate an instance, any data on instance store volumes is lost. For more information, see Amazon EC2 Instance Store (p. 582).

Amazon S3

Amazon S3 is a repository for Internet data. Amazon S3 provides access to reliable and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. For example, you can use Amazon S3 to store backup copies of your data and applications. For more information, see Amazon Simple Storage Service (Amazon S3) (p. 590).

Adding Storage

Every time you launch an instance from an AMI, a root storage device is created for that instance. The root storage device contains all the information necessary to boot the instance. You can specify storage volumes in addition to the root device volume when you create an AMI or launch an instance using block device mapping. For more information, see Block Device Mapping (p. 592).
You can also attach EBS volumes to a running instance. For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529).

Amazon Elastic Block Store (Amazon EBS)

Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with Amazon EC2 instances. Amazon EBS volumes are highly available and reliable storage volumes that can be attached to any running instance that is in the same Availability Zone. Amazon EBS volumes that are attached to an Amazon EC2 instance are exposed as storage volumes that persist independently from the life of the instance. With Amazon EBS, you pay only for what you use. For more information about Amazon EBS pricing, see the Projecting Costs section of the Amazon Elastic Block Store page.

Amazon EBS is recommended when data changes frequently and requires long-term persistence. Amazon EBS volumes are particularly well-suited for use as the primary storage for file systems, databases, or for any applications that require fine granular updates and access to raw, unformatted, block-level storage. Amazon EBS is particularly helpful for database-style applications that frequently encounter many random reads and writes across the data set.

You can attach multiple volumes to the same instance within the limits specified by your AWS account. Your account has a limit on the number of Amazon EBS volumes that you can use, and the total storage available to you. For more information about these limits, and how to request an increase in your limits, see Request to Increase the Amazon EBS Volume Limit.

Features of Amazon EBS

• You can create Amazon EBS storage volumes from 1 GB to 1 TB in size and mount them as devices on your Amazon EC2 instances. You can mount multiple volumes on the same instance, but each volume can be attached to only one instance at a time. For more information, see Creating a New Amazon EBS Volume (p. 526).
• With Amazon EBS provisioned IOPS (input/output operations per second) volumes, you can provision a specific level of I/O performance, up to 4000 IOPS per volume. This allows you to predictably scale to thousands of IOPS per Amazon EC2 instance. For more information, see Provisioned IOPS Volumes (p. 526).
• Amazon EBS volumes behave like raw, unformatted block devices. You can create a file system on top of these volumes, or use them in any other way you would use a block device (like a hard drive). For more information on creating file systems and mounting volumes, see Making an Amazon EBS Volume Available for Use (p. 532).
• You can create point-in-time snapshots of Amazon EBS volumes, which are persisted to Amazon S3. Snapshots protect data for long-term durability, and they can be used as the starting point for new Amazon EBS volumes. The same snapshot can be used to instantiate as many volumes as you wish. These snapshots can be copied across AWS regions. For more information, see Amazon EBS Snapshots (p. 559).
• Amazon EBS volumes are created in a specific Availability Zone, and can then be attached to any instances in that same Availability Zone. To make a volume available outside of the Availability Zone, you can create a snapshot and restore that snapshot to a new volume anywhere in that region.
can copy snapshots to other regions and then restore them to new volumes there, making it easier to leverage multiple AWS regions for geographical expansion, data center migration, and disaster recovery. For more information, see Creating an Amazon EBS Snapshot (p. 559), Restoring an Amazon EBS Volume from a Snapshot (p. 528), and Copying an Amazon EBS Snapshot (p. 561).

- A large repository of public data set snapshots can be restored to Amazon EBS volumes and seamlessly integrated into AWS cloud-based applications. For more information, see Using Public Data Sets (p. 603).
- Performance metrics, such as bandwidth, throughput, latency, and average queue length, are available through the AWS Management Console. These metrics, provided by Amazon CloudWatch, allow you to monitor the performance of your volumes to make sure that you are providing enough performance for your applications without paying for resources you don’t need. For more information, see Amazon EBS Volume Performance (p. 564).

## Amazon EBS Volumes

An Amazon EBS volume is a durable, block-level storage device that you can attach to a single EC2 instance. You can use Amazon EBS volumes as primary storage for data that requires frequent updates, such as the system drive for an instance or storage for a database application. Amazon EBS volumes persist independently from the running life of an EC2 instance. After a volume is attached to an instance, you can use it like any other physical hard drive. Amazon EBS provides two volume types: Standard and Provisioned IOPS. They differ in performance characteristics and price, allowing you to tailor your storage performance and cost to the needs of your applications. For more information, see Amazon EBS Volume Types (p. 525).

## Benefits of Using Amazon EBS Volumes

### Data Availability

When you create an Amazon EBS volume in an Availability Zone, it is automatically replicated within that zone to prevent data loss due to failure of any single hardware component. After you create a volume, you can attach it to any Amazon EC2 instance in the same Availability Zone. After you attach a volume, it appears as a native block device similar to a hard drive or other physical device. At that point, the instance can interact with the volume just as it would with a local drive; the instance can format the Amazon EBS volume with a file system such as ext3 (Linux) or NTFS (Windows) and install applications.

An Amazon EBS volume can be attached to only one instance at a time within the same Availability Zone. However, multiple volumes can be attached to a single instance. If you attach multiple volumes to a device that you have named, you can stripe data across the volumes for increased I/O and throughput performance.
You can get monitoring data for your Amazon EBS volumes at no additional charge (this includes data for the root device volumes for Amazon EBS-backed instances). For more information, see Monitoring Volumes with CloudWatch (p. 536).

**Data Persistence**

An Amazon EBS volume is off-instance storage that can persist independently from the life of an instance. You continue to pay for the volume usage as long as the data persists.

By default, Amazon EBS volumes that are attached to a running instance automatically detach from the instance with their data intact when that instance is terminated. The volume can then be reattached to a new instance, enabling quick recovery. If you are using an Amazon EBS-backed instance, you can stop and restart that instance without affecting the data stored in the attached volume. The volume remains attached throughout the stop-start cycle. This enables you to process and store the data on your volume indefinitely, only using the processing and storage resources when required. The data persists on the volume until the volume is deleted explicitly. After a volume is deleted, it can't be attached to any instance. The physical block storage used by deleted Amazon EBS volumes is overwritten with zeroes before it is allocated to another customer. If you are dealing with sensitive data, you should consider encrypting your data.

By default, Amazon EBS volumes that are created and attached to an instance at launch are deleted when that instance is terminated. You can modify this behavior by changing the value of the flag `DeleteOnTermination` to `false` when you launch the instance. This modified value causes the volume to persist even after the instance is terminated, and enables you to attach the volume to another instance.

**Snapshots**

Amazon EBS provides the ability to create snapshots (backups) of any Amazon EC2 volume and write a copy of the data in the volume to Amazon S3, where it is stored redundantly in multiple Availability Zones. The volume does not need to be attached to a running instance in order to take a snapshot. As you continue to write data to a volume, you can periodically create a snapshot of the volume to use as a baseline for new volumes. These snapshots can be used to create multiple new Amazon EBS volumes, expand the size of a volume, or move volumes across Availability Zones.

When you create a new volume from a snapshot, it's an exact copy of the original volume at the time the snapshot was taken. By optionally specifying a different volume size or a different Availability Zone, you can use this functionality to increase the size of an existing volume or to create duplicate volumes in new Availability Zones. The snapshots can be shared with specific AWS accounts or made public. When you create snapshots, you incur charges in Amazon S3 based on the volume's total size. For a successive snapshot of the volume, you are only charged for any additional data beyond the volume's original size.

Amazon EBS snapshots are incremental backups, meaning that only the blocks on the volume that have changed after your most recent snapshot are saved. If you have a volume with 100 GiB of data, but only 5 GiB of data have changed since your last snapshot, only the 5 GiB of modified data is written to Amazon S3. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to restore the volume.

To help categorize and manage your volumes and snapshots, you can tag them with metadata of your choice. For more information, see Tagging Your Amazon EC2 Resources (p. 610).

**Amazon EBS Volume Types**

Amazon EBS provides two volume types: Standard and Provisioned IOPS (input/output operations per second). They differ in performance characteristics and price, allowing you to tailor your storage performance and cost to the needs of your applications.

**Standard Volumes**
Standard volumes offer cost effective storage that is ideal for applications with light or bursty I/O requirements. These volumes deliver approximately 100 IOPS on average, with burst capability of up to hundreds of IOPS, and they can range in size from 1 GB to 1 TB. Standard volumes can be striped together in a RAID configuration for larger size and greater performance. The following example usage scenarios work well with Amazon EBS standard volumes:

- File server
- Log processing
- Low-traffic websites
- Analytics
- System boot volume

**Provisioned IOPS Volumes**

Provisioned IOPS volumes are designed to meet the needs of I/O-intensive workloads, particularly database workloads, that are sensitive to storage performance and consistency in random access I/O throughput. You specify an IOPS rate when you create the volume, and Amazon EBS delivers within 10 percent of the provisioned IOPS performance 99.9 percent of the time over a given year.

A Provisioned IOPS volume can range in size from 10 GB to 1 TB and you can provision up to 4000 IOPS per volume. The ratio of IOPS provisioned to the volume size requested can be a maximum of 30; for example, a volume with 3000 IOPS must be at least 100 GB. You can stripe multiple volumes together in a RAID configuration for larger size and greater performance. The following example usage scenarios work well with Amazon EBS Provisioned IOPS volumes:

- Business applications
- Database workloads, such as:
  - MongoDB
  - Microsoft SQL Server
  - MySQL
  - PostgreSQL
  - Oracle

There are several factors that can affect the performance of Amazon EBS volumes, such as instance configuration, I/O characteristics, and workload demand. For more information about getting the most out of your Provisioned IOPS volumes, see Amazon EBS Volume Performance (p. 564).

**Creating a New Amazon EBS Volume**

You can create a new Amazon EBS volume that you can then attach to any Amazon EC2 instance within the same Availability Zone.

You can also create and attach Amazon EBS volumes when you launch instances by specifying a block device mapping. For more information, see Launching an Instance (p. 300) and Block Device Mapping (p. 592). You can restore volumes from previously created snapshots. For more information, see Restoring an Amazon EBS Volume from a Snapshot (p. 528).

If you are creating a volume for a high-performance storage scenario, you should make sure to use a provisioned IOPS volume and attach it to an instance with enough bandwidth to support your application, such as an EBS-optimized instance or an instance with 10 Gigabit network connectivity. For more information, see Amazon EC2 Instance Configuration (p. 565).

When a block of data on a newly created Amazon EBS volume is written to for the first time, you might experience longer than normal latency. To avoid the possibility of an increased write latency on a production
workload, you should first write to all blocks on the volume to ensure optimal performance; this practice is called pre-warming the volume. For more information, see Pre-Warming Amazon EBS Volumes (p. 568).

To create a new Amazon EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the region in which you would like to create your volume. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. For more information, see Resource Locations (p. 606).

3. Click Volumes in the navigation pane.
4. Above the upper pane, click Create Volume.
5. In the Create Volume dialog box, in the Volume Type list, select Standard or Provisioned IOPS. For more information, see Amazon EBS Volume Types (p. 525).
6. In the Size box, enter the size of the volume in GiB.
7. For Provisioned IOPS volumes, in the IOPS box, enter the maximum number of input/output operations per second (IOPS) that the volume should support.
8. In the Availability Zone list, select the Availability Zone in which to create the volume. For more information, see Regions and Availability Zones (p. 7).
9. Click Yes, Create.

To create a new Amazon EBS volume using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- create-volume (AWS CLI)
- ec2-create-volume (Amazon EC2 CLI)
- New-EC2Volume (AWS Tools for Windows PowerShell)
Restoring an Amazon EBS Volume from a Snapshot

You can restore an Amazon EBS volume with data from a snapshot stored in Amazon S3. You need to know the ID of the snapshot you wish to restore your volume from and you need to have access permissions for the snapshot. For more information on snapshots, see Amazon EBS Snapshots (p. 559).

New volumes created from existing Amazon S3 snapshots load lazily in the background. This means that after a volume is created from a snapshot, there is no need to wait for all of the data to transfer from Amazon S3 to your Amazon EBS volume before your attached instance can start accessing the volume and all its data. If your instance accesses data that hasn't yet been loaded, the volume immediately downloads the requested data from Amazon S3, and continues loading the rest of the data in the background.

When a block of data on a newly restored Amazon EBS volume is accessed for the first time, you might experience longer than normal latency. To avoid the possibility of increased read or write latency on a production workload, you should first access all of the blocks on the volume to ensure optimal performance; this practice is called pre-warming the volume. For more information, see Pre-Warming Amazon EBS Volumes (p. 568).

To restore an Amazon EBS volume from a snapshot using the console

You can restore your Amazon EBS volume from a snapshot using the AWS Management Console as follows.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the region that your snapshot is located in. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. For more information, see Resource Locations (p. 606). If you need to restore the snapshot to a volume in a different region, you can copy your snapshot to the new region and then restore it to a volume in that region. For more information, see Copying an Amazon EBS Snapshot (p. 561).
3. Click Volumes in the navigation pane.
4. Above the upper pane, click Create Volume.
5. In the Create Volume dialog box, in the Volume Type list, select Standard or Provisioned IOPS. For more information, see Amazon EBS Volume Types (p. 525).
6. In the **Snapshot** field, start typing the ID or description of the snapshot from which you are restoring the volume, and select it from the list of suggested options.

7. In the **Size** box, enter the size of the volume in GiB, or verify that the default size of the snapshot is adequate.

   **Note**
   If you specify both a volume size and a snapshot ID, the size must be equal to or greater than the snapshot size. When you select a volume type and a snapshot ID, minimum and maximum sizes for the volume are shown next to the **Size** list. Any AWS Marketplace product codes from the snapshot are propagated to the volume.

8. For Provisioned IOPS volumes, in the **IOPS** box, enter the maximum number of input/output operations per second (IOPS) that the volume can support.

9. In the **Availability Zone** list, select the Availability Zone in which to create the volume. For more information, see Regions and Availability Zones (p. 7).

10. Click **Yes, Create**.

    **Important**
    If you restored a snapshot to a larger volume than the default for that snapshot, you need to extend the file system on the volume to take advantage of the extra space. For more information, see Expanding the Storage Space of a Volume (p. 548).

To restore a new Amazon EBS volume using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `create-volume` (AWS CLI)
- `ec2-create-volume` (Amazon EC2 CLI)
- `New-EC2Volume` (AWS Tools for Windows PowerShell)

**Attaching an Amazon EBS Volume to an Instance**

This section describes how to attach an Amazon EBS volume that you created to an instance.

To attach an Amazon EBS volume to an instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Click **Volumes** in the navigation pane.
   
   The console displays a list of current volumes.
3. Select a volume and click **Attach Volume**.
   
   The **Attach Volume** dialog box appears.
4. In the **Instance** box, start typing the name or ID of the instance to attach the volume to, and select it from the list of suggestion options (only instances in the same Availability Zone as the volume are displayed).
5. Verify that the suggested device name is suitable, or enter a device name in the **Device** box. For more information on naming conventions and restrictions, see Device Naming (p. 530).
6. Click **Attach** to attach the volume to the instance. The volume and instance must be in the same Availability Zone.

If a volume has an AWS Marketplace product code:

- The volume can only be attached to the root device of a stopped instance.
• You must be subscribed to the AWS Marketplace code that is on the volume.
• The configuration (instance type, operating system) of the instance must support that specific AWS Marketplace code. For example, you cannot take a volume from a Windows instance and attach it to a Linux instance.
• AWS Marketplace product codes are copied from the volume to the instance.

To attach an Amazon EBS volume to an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- attach-volume (AWS CLI)
- ec2-attach-volume (Amazon EC2 CLI)
- Add-EC2Volume (AWS Tools for Windows PowerShell)

Device Naming

The following table lists the available device names on Amazon EC2. You can specify these names when attaching a volume to a running instance or when launching an instance using a block device mapping. The block device driver for the instance assigns the actual volume names when mounting the volumes, and these names can be different than the names that Amazon EC2 recommends. For more information about instance store volumes, see Amazon EC2 Instance Store (p. 582). For information about the root device storage, see Amazon EC2 Root Device Volume (p. 13).

Depending on the block device driver of your instance’s kernel, the device may be attached with a different name than what you specify. For example, if you specify a device name of /dev/sdh, your device may be renamed /dev/xvhd or /dev/hdh by the kernel; in some cases, even the trailing letter may also change (where /dev/sda could become /dev/xvde). Amazon Linux AMIs create a symbolic link from the renamed device path to the name you specify, but other AMIs may behave differently.
Important
You cannot attach volumes that share the same device letters both with and without trailing digits. For example, if you attach a volume as /dev/sdc and another volume as /dev/sdc1, only /dev/sdc will be visible to the instance. If you wish use trailing digits in device names, you must use trailing digits on all device names that share the same base letters (such as /dev/sdc1, /dev/sdc2, /dev/sdc3).

For Linux/Unix instance types, we’ve received reports that some custom kernels might have restrictions that limit use to /dev/sd[f-p] or /dev/sd[f-p][1-6]. If you’re having trouble using /dev/sd[q-z] or /dev/sd[q-z][1-6], try switching to /dev/sd[f-p] or /dev/sd[f-p][1-6].

Hardware virtual machine (HVM) AMIs (such as Windows and Cluster Compute images) do not support the use of trailing numbers on device names (xvd[a-p][1-15]). You can view the virtualization type of your instance on the Virtualization field of the instance’s details pane.

Depending on the size of your instance, Amazon EC2 provides instance store volumes on /dev/sd[b-e] (on Linux/Unix) or xvd[a-e]. Although you can connect your Amazon EBS volumes using these device names, we highly recommend that you don’t because the behavior can be unpredictable.

Amazon EC2 Windows AMIs come with an additional service installed, the Ec2Config Service. The Ec2Config service runs as a local system and performs various functions to prepare an instance when it first boots up. After the devices have been mapped with the drives, the Ec2Config service then initializes and mounts the drives. The root drive is initialized and mounted as c: \. The instance store volumes that come attached to the instance are initialized and mounted as d: \, e: \, and so on. By default, when an Amazon EBS volume is attached to a Windows instance, it may show up as any drive letter on the instance. You can change the settings of the Ec2Config service to set the drive letters of the Amazon EBS volumes per your specifications. For more information, see Using Ec2Config in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

Volume Limits
Although Amazon EC2 does not impose limitations on how many volumes you can attach to an instance, there are several factors you need to consider when attaching multiple volumes. The upper limit of volumes you should attach to your instance is dependent on your operating system (Linux instances can reliably handle more volumes than Windows instances). Another consideration is whether your desired effect is increased I/O bandwidth or increased storage capacity.

Windows-specific Volume Limits
Windows instances use either Red Hat or Citrix paravirtual (PV) drivers for storage I/O, and each driver type has its own upper limit for volume attachment. If your Windows instance is using Citrix PV drivers, you can attach up to a total of 25 Amazon EBS volumes using the Amazon EC2 CLI; Windows instances with Red Hat PV drivers are limited to 16 volumes. Regardless of which drivers you are using, you can attach up to 16 Amazon EBS volumes using the Amazon EC2 console. To determine which paravirtual drivers your instance is using or to upgrade your Windows instance from Red Hat to Citrix paravirtual drivers, see Upgrading Your PV Drivers on Your Windows AMI.

Although it is technically possible to attach more than 25 volumes to a Windows instance with Citrix PV drivers, this is likely to cause performance issues and is not recommended.

Bandwidth vs Capacity
For consistent and predictable bandwidth use cases, use EBS-optimized or 10 Gigabit network connectivity instances and Provisioned IOPS volumes. Follow the guidance in the Amazon EC2 Instance Configuration (p. 565) topic to match the IOPS you have provisioned for your volumes to the bandwidth available from your instances for maximum performance. For RAID configurations, many administrators find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead; test your individual application performance and tune it as required.
For increased capacity use cases, you can attach many more volumes, but attaching more than 40 volumes (this quantity is only possible on Linux instances; see Windows-specific Volume Limits (p. 531) for Windows instances) may result in boot failures. If you experience boot problems on an instance with many volumes attached, you can stop the instance, detach the non-essential boot volumes, and then reattach them after the instance is running.

Making an Amazon EBS Volume Available for Use

After you attach an Amazon EBS volume to your instance, it is exposed as a block device. You can format the volume with any file system and then mount it. After you make the Amazon EBS volume available for use, you can access it in the same ways that you access any other volume. You can also take snapshots of your Amazon EBS volume for backup purposes or to use as a baseline when you create another volume.

Topics
- Making the Volume Available on Linux (p. 532)
- Make the Volume Available on Windows (p. 534)

Making the Volume Available on Linux

To make an Amazon EBS volume available for use on Linux

1. Connect to your instance using SSH. For more information, see Connect to Your Instance (p. 26).
2. Depending on the block device driver of your instance's kernel, the device may be attached with a different name than what you specify. For example, if you specify a device name of /dev/sdh, your device may be renamed /dev/xvdh or /dev/hdh by the kernel; in some cases, even the trailing letter may also change (where /dev/sda could become /dev/xvde). Amazon Linux AMIs create a symbolic link from the renamed device path to the name you specify, but other AMIs may behave differently.

Use the `lsblk` command to view your available disk devices and their mount points (if applicable) to help you determine the correct device name to use.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
xvdf   202:80  0   100G 0 disk
xvda1  202:1   0    8G  0 disk /
```

The output of `lsblk` removes the /dev/ prefix from full device paths. In this example, /dev/xvda1 is mounted as the root device (note the MOUNTPOINT is listed as /, the root of the Linux file system hierarchy), and /dev/xvdf is attached, but it has not been mounted yet.

3. Determine if you need to create a file system on the volume. New volumes are raw block devices, and you need to create a file system on them before you can mount and use them. Volumes that have been restored from snapshots likely have a file system on them already; if you create a new file system on top of an existing file system, the operation overwrites your data. Use the `sudo file -s device` command to list special information, such as file system type.

```
[ec2-user ~]$ sudo file -s /dev/xvdf
/dev/xvdf: data
```

If the output of the previous command shows simply data for the device, then there is no file system on the device and you need to create one. You can go on to Step 4 (p. 533). If you run this command on a device that contains a file system, then your output will be different.
In the above example, the device contains Linux rev 1.0 ext4 filesystem data, so this volume does not need a file system created (you can skip Step 4 (p. 533) if your output shows file system data).

4. (Optional) Use the following command to create an ext4 file system on the volume. Substitute the device name (such as /dev/xvdf) for device_name. Depending on the requirements of your application or the limitations of your operating system, you may opt for a different file system type, such as ext3 or XFS.

**Caution**

This step assumes that you're mounting an empty volume. If you're mounting a volume that already has data on it (for example, a volume that was restored from a snapshot), don't use mkfs before mounting the volume (skip to the next step instead). Otherwise, you'll format the volume and delete the existing data.

5. Use the following command to create a mount point directory for the volume. The mount point is where the volume is located in the file system tree and where you read and write files to after you mount the volume. Substitute a location for mount_point, such as /data.

6. Use the following command to mount the volume at the location you just created.

7. (Optional) To mount this Amazon EBS volume on every system reboot, add an entry for the device to the /etc/fstab file.

   a. Create a backup of your /etc/fstab file that you can use if you accidentally destroy or delete this file while you are editing it.

   b. Open the /etc/fstab file using your favorite text editor, such as nano or vim.

   c. Add a new line to the end of the file for your volume using the following format.

   ```bash
   device_name mount_point file_system_type fs_mntops fs_freq fs_passno
   ```

   The last three fields on this line are the file system mount options, the dump frequency of the file system, and the order of file system checks done at boot time. If you don't know what these values should be, then use the values in the example below for them (defaults 0 2). For more information on /etc/fstab entries, see the `fstab` manual page (by entering `man fstab` on the command line). For example, to mount the ext4 file system on the device /dev/xvdf at the mount point /data, add the following entry to /etc/fstab.
After you've added the new entry to /etc/fstab, you need to check that your entry works. Run the `sudo mount -a` command to mount all file systems in /etc/fstab.

```
[ec2-user ~]$ sudo mount -a
```

If the above command does not produce an error, then your /etc/fstab file is OK and your file system will mount automatically at the next boot. If the command does produce any errors, examine the errors and try to correct your /etc/fstab.

**Warning**

Errors in the /etc/fstab file can render a system unbootable. Do not shut down a system that has errors in the /etc/fstab file.

e. (Optional) If you are unsure how to correct /etc/fstab errors, you can always restore your backup /etc/fstab file with the following command.

```
[ec2-user ~]$ sudo mv /etc/fstab.orig /etc/fstab
```

## Make the Volume Available on Windows

**To use an Amazon EBS volume**

1. Log in to your instance using Remote Desktop.
2. • Windows Server 2012: Go to the Start screen.
   • Windows Server 2008: On the taskbar, click Start, and then click Run.
3. Type `diskmgmt.msc` and press Enter. The Disk Management utility opens.

   **Caution**

   If you're mounting a volume that already has data on it (for example, a public data set), make sure you don't reformat the volume and delete the existing data.

4. Select the disk that represents the new Amazon EBS volume.
5. On the **Disk Management** menu, select **Action - All Tasks - Online**.

6. A new disk needs to be initialized before it can be used. To initialize the disk:
   a. In the Disk Management utility, select the new Amazon EBS volume disk.
   b. On the **Disk Management** menu, select **Action - All Tasks - Initialize Disk**.
   c. In the **Initialize Disk** dialog, select the disk to initialize, select the desired partition style, and press **OK**.

Your new Amazon EBS volume is now available for use. Any data written to this file system is written to the Amazon EBS volume and is transparent to applications using the device.
**Viewing Volume Information**

You can view descriptive information for all of your volumes in a selected region at a time in the AWS Management Console. You can also view detailed information about a single volume, including the size, volume type, and the specific instance to which the volume is attached.

**To view information about an Amazon EBS volume using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click **Volumes** in the navigation pane.
   - The console displays a list of current volumes and the instances they are attached to.
3. To view more information about a volume, select it.
   - Information about the volume appears in the lower pane.

**To view information about an Amazon EBS volume using the command line**

You can use one of the following commands. For more information about these command line interfaces, see **Accessing Amazon EC2** (p. 3).

- `describe-volumes` (AWS CLI)
- `ec2-describe-volumes` (Amazon EC2 CLI)
- `Get-EC2Volume` (AWS Tools for Windows PowerShell)

**Monitoring the Status of Your Volumes**

Amazon Web Services (AWS) automatically provides data, such as Amazon CloudWatch metrics and volume status checks, that you can use to monitor your Amazon Elastic Block Store (Amazon EBS) volumes.

**Topics**

- Monitoring Volumes with CloudWatch (p. 536)
- Monitoring Volumes with Status Checks (p. 539)
- Monitoring Volume Events (p. 541)
- Working with an Impaired Volume (p. 542)
- Working with the AutoEnableIO Volume Attribute (p. 544)

**Monitoring Volumes with CloudWatch**

CloudWatch metrics are statistical data that you can use to view, analyze, and set alarms on the operational behavior of your volumes.

The following table describes the types of monitoring data available for your Amazon EBS volumes.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic</td>
<td>Data is available automatically in 5-minute periods at no charge. This includes data for the root device volumes for Amazon EBS-backed instances.</td>
</tr>
<tr>
<td>Detailed</td>
<td>Provisioned IOPS volumes automatically send one-minute metrics to CloudWatch.</td>
</tr>
</tbody>
</table>
When you get data from CloudWatch, you can include a `Period` request parameter to specify the granularity of the returned data. This is different than the period that we use when we collect the data (5-minute periods). We recommend that you specify a period in your request that is equal to or larger than the collection period to ensure that the returned data is valid.

You can get the data using either the Amazon CloudWatch API or the Amazon EC2 console. The console takes the raw data from the Amazon CloudWatch API and displays a series of graphs based on the data. Depending on your needs, you might prefer to use either the data from the API or the graphs in the console.

**Amazon EBS Metrics**

You can use the Amazon CloudWatch `GetMetricStatistics` API to get any of the Amazon EBS volume metrics listed in the following table. Similar metrics are grouped together in the table, and the metrics in the first two rows are also available for the local stores on Amazon EC2 instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumeReadBytes</td>
<td>The total number of bytes transferred in a specified period of time. Data is only reported to Amazon CloudWatch when the volume is active. If the volume is idle, no data is reported to Amazon CloudWatch.</td>
</tr>
<tr>
<td>VolumeWriteBytes</td>
<td></td>
</tr>
<tr>
<td>VolumeReadOps</td>
<td>The total number of I/O operations in a specified period of time. <strong>Note</strong> To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period.</td>
</tr>
<tr>
<td>VolumeWriteOps</td>
<td></td>
</tr>
<tr>
<td>VolumeTotalReadTime</td>
<td>The total number of seconds spent by all operations that completed in a specified period of time. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, for a period of 5 minutes (300 seconds): if 700 operations completed during that period, and each operation took 1 second, the value would be 700 seconds.</td>
</tr>
<tr>
<td>VolumeTotalWriteTime</td>
<td></td>
</tr>
<tr>
<td>VolumeIdleTime</td>
<td>The total number of seconds in a specified period of time when no read or write operations were submitted.</td>
</tr>
<tr>
<td>VolumeQueueLength</td>
<td>The number of read and write operation requests waiting to be completed in a specified period of time.</td>
</tr>
</tbody>
</table>

Units: Bytes, Count, Seconds
### DescriptionMetric

**VolumeThroughputPercentage**

Used with Provisioned IOPS volumes only. The percentage of I/O operations per second (IOPS) delivered of the total IOPS provisioned for an Amazon EBS volume. Provisioned IOPS volumes deliver within 10 percent of the provisioned IOPS performance 99.9 percent of the time over a given year.

**Note**

During a write, if there are no other pending I/O requests in a minute, the metric value will be 100 percent. Also, a volume's I/O performance may become degraded temporarily due to an action you have taken (e.g., creating a snapshot of a volume during peak usage, running the volume on a non-EBS-optimized instance, accessing data on the volume for the first time).

**Units:** Percent

### VolumeConsumedReadWriteOps

Used with Provisioned IOPS volumes only. The total amount of read and write operations (normalized to 16K capacity units) consumed in a specified period of time.

I/O operations that are smaller than 16K each count as 1 consumed IOPS. I/O operations that are larger than 16K are counted in 16K capacity units. For example, a 64K I/O would count as 4 consumed IOPS.

**Units:** Count

### Graphs in the Amazon EC2 console

After you create a volume, you can go to the Amazon EC2 console and view the volume's monitoring graphs. They're displayed when you select the volume on the Volumes page in the EC2 console. A Monitoring tab is displayed next to the volume's Description tab. The following table lists the graphs that are displayed. The column on the right describes how the raw data metrics from the Amazon CloudWatch API are used to produce each graph. The period for all the graphs is 5 minutes.

<table>
<thead>
<tr>
<th>Graph Name</th>
<th>Description Using Raw Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read Bandwidth (KiB/s)</td>
<td>Sum(VolumeReadBytes) / Period / 1024</td>
</tr>
<tr>
<td>Write Bandwidth (KiB/s)</td>
<td>Sum(VolumeWriteBytes) / Period / 1024</td>
</tr>
<tr>
<td>Read Throughput (Ops/s)</td>
<td>Sum(VolumeReadOps) / Period</td>
</tr>
<tr>
<td>Write Throughput (Ops/s)</td>
<td>Sum(VolumeWriteOps) / Period</td>
</tr>
<tr>
<td>Avg Queue Length (ops)</td>
<td>Avg(VolumeQueueLength)</td>
</tr>
<tr>
<td>% Time Spent Idle</td>
<td>Sum(VolumenIdleTime) / Period * 100</td>
</tr>
<tr>
<td>Avg Read Size (KiB/op)</td>
<td>Avg(VolumeReadBytes) / 1024</td>
</tr>
<tr>
<td>Avg Write Size (KiB/op)</td>
<td>Avg(VolumeWriteBytes) / 1024</td>
</tr>
<tr>
<td>Avg Read Latency (ms/op)</td>
<td>Avg(VolumeTotalReadTime) * 1000</td>
</tr>
<tr>
<td>Avg Write Latency (ms/op)</td>
<td>Avg(VolumeTotalWriteTime) * 1000</td>
</tr>
</tbody>
</table>
For the average latency graphs and average size graphs, the average is calculated over the total number of operations (read or write, whichever is applicable to the graph) that completed during the period.

The AWS Management Console contains a console for Amazon CloudWatch. In the Amazon CloudWatch console you can search and browse all your AWS resource metrics, view graphs to troubleshoot issues and discover trends, create and edit alarms to be notified of problems, and see at-a-glance overviews of your alarms and AWS resources. For more information, see AWS Management Console in the Amazon CloudWatch Developer Guide.

**Monitoring Volumes with Status Checks**

Volume status checks enable you to better understand, track, and manage potential inconsistencies in the data on an Amazon EBS volume. They are designed to provide you with the information that you need to determine whether your Amazon EBS volumes are impaired, and to help you control how a potentially inconsistent volume is handled.

Volume status checks are automated tests that return a pass or fail status. If all checks pass, the status of the volume is `ok`. If a check fails, the status of the volume is `impaired`. If the status is `insufficient-data`, the checks may still be in progress on the volume. You can view the results of volume status checks to identify any impaired volumes and take any necessary actions.

When Amazon EBS determines that a volume's data is potentially inconsistent, the default is that it disables I/O to the volume from any attached EC2 instances, which helps to prevent data corruption. After I/O is disabled, the next volume status check fails, and the volume status is `impaired`. In addition, you'll see an event that lets you know that I/O is disabled, and that you can resolve the impaired status of the volume by enabling I/O to the volume. We wait until you enable I/O to give you the opportunity to decide whether to continue to let your instances use the volume, or to run a consistency check using a command such as `fsck` (Linux/Unix) or `chkdsk` (Windows) before doing so.

**Note**

Volume status is based on the volume status checks, and does not reflect the volume state. Therefore, volume status does not indicate volumes in the `error` state (for example, when a volume is incapable of accepting I/O.)

If the consistency of a particular volume is not a concern for you, and you'd prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the `AutoEnableIO` volume attribute, the volume status check continues to pass. In addition, you'll see an event that lets you know that the volume was determined to be potentially inconsistent, but that its I/O was automatically enabled. This enables you to check the volume's consistency or replace it at a later time.

The following table lists statuses for standard and provisioned IOPS volumes.

To view and work with status checks, you can use the Amazon EC2 console, the API, or the command line interface.

**To view status checks in the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Volumes.
3. On the EBS Volumes page, the Volume Status column lists the operational status of each volume.
4. To view an individual volume’s status, select the volume, and then click the Status Checks tab.
5. If you have a volume with a failed status check (status is impaired), see Working with an Impaired Volume (p. 542).

Alternatively, you can use the Events pane to view all events for your instances and volumes in a single pane. For more information, see Monitoring Volume Events (p. 541).

**To view volume status information with the command line**

You can use one of the following commands to view the status of your Amazon EBS volumes. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-volume-status` (AWS CLI)
- `ec2-describe-volume-status` (Amazon EC2 CLI)
- `Get-EC2VolumeStatus` (AWS Tools for Windows PowerShell)
Monitoring Volume Events

When Amazon EBS determines that a volume’s data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure.

To automatically enable I/O on a volume with potential data inconsistencies, change the setting of the `AutoEnableIO` volume attribute. For more information about changing this attribute, see Working with an Impaired Volume (p. 542).

Each event includes a start time that indicates the time at which the event occurred, and a duration that indicates how long I/O for the volume was disabled. The end time is added to the event when I/O for the volume is enabled.

Volume status events include one of the following descriptions:

**Awaiting Action: Enable IO**
- Volume data is potentially inconsistent. I/O is disabled for the volume until you explicitly enable it. The event description changes to **IO Enabled** after you explicitly enable I/O.

**IO Enabled**
- I/O operations were explicitly enabled for this volume.

**IO Auto-Enabled**
- I/O operations were automatically enabled on this volume after an event occurred. We recommend that you check for data inconsistencies before continuing to use the data.

**Normal**
- For provisioned IOPS volumes only. Volume performance is as expected.

**Degraded**
- For provisioned IOPS volumes only. Volume performance is below expectations.

**Severely Degraded**
- For provisioned IOPS volumes only. Volume performance is well below expectations.

**Stalled**
- For provisioned IOPS volumes only. Volume performance is severely impacted.

You can view events for your volumes using the Amazon EC2 console, the API, or the command line interface.

To view events for your volumes in the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click **Events**.
3. All instances and volumes that have events are listed. You can filter by volume to view only volume status. You can also filter on specific status types.
4. Select a volume to view its specific event.
If you have a volume where I/O is disabled, see Working with an Impaired Volume (p. 542). If you have a volume where I/O performance is below normal, this might be a temporary condition due to an action you have taken (e.g., creating a snapshot of a volume during peak usage, running the volume on an instance that cannot support the I/O bandwidth required, accessing data on the volume for the first time, etc.).

To view events for your volumes with the command line

You can use one of the following commands to view event information for your Amazon EBS volumes. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `describe-volume-status` (AWS CLI)
- `ec2-describe-volume-status` (Amazon EC2 CLI)
- `Get-EC2VolumeStatus` (AWS Tools for Windows PowerShell)

Working with an Impaired Volume

This section discusses your options if a volume is impaired because the volume’s data is potentially inconsistent.

Topics

- Option 1: Perform a Consistency Check on the Volume Attached to its Instance (p. 542)
- Option 2: Perform a Consistency Check on the Volume Using Another Instance (p. 543)
- Option 3: Delete the Volume If You No Longer Need It (p. 544)

Option 1: Perform a Consistency Check on the Volume Attached to its Instance

The simplest option is to enable I/O and then perform a data consistency check on the volume while the volume is still attached to its Amazon EC2 instance.

To perform a consistency check on an attached volume

1. Stop any applications from using the volume.
2. Enable I/O on the volume.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, click Volumes.
   c. Select the volume on which you want to enable I/O operations.
   d. In the details pane, click Enable Volume IO.
   e. In Enable Volume IO, click Yes, Enable.

3. Check the data on the volume.
   a. Run the fsck (Linux) or chkdsk (Windows) command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes you can contact support. Click Troubleshoot, and then on the Troubleshoot Status Checks dialog box, click Contact Support to submit a support case.

For information about using the command line interface to enable I/O for a volume, see ec2-enable-volume-io in the Amazon Elastic Compute Cloud Command Line Reference. For information about using the API to enable I/O for a volume, see EnableVolumeIO in the Amazon Elastic Compute Cloud API Reference.

Option 2: Perform a Consistency Check on the Volume Using Another Instance

Use the following procedure to check the volume outside your production environment.

Important
This procedure may cause the loss of write I/Os that were suspended when volume I/O was disabled.

To perform a consistency check on a volume in isolation
1. Stop any applications from using the volume.
2. Detach the volume from the instance.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, click Volumes.
   c. Select the volume that you want to detach.
   d. Click Actions, and then click Force Detach Volume. You'll be prompted for confirmation.
3. Enable I/O on the volume.
   a. In the navigation pane, click Volumes.
   b. Select the volume that you detached in the previous step.
   c. In the details pane, click Enable Volume IO.
   d. In the Enable Volume IO dialog box, click Yes, Enable.

4. Attach the volume to another instance. For information, see Launch Your Instance (p. 300) and Attaching an Amazon EBS Volume to an Instance (p. 529).

5. Check the data on the volume.
   a. Run the fsck (Linux) or chkdsk (Windows) command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact support. Click Troubleshoot, and then in the troubleshooting dialog box, click Contact Support to submit a support case.

For information about using the command line interface to enable I/O for a volume, see ec2-enable-volume-io in the Amazon Elastic Compute Cloud Command Line Reference. For information about using the API to enable I/O for a volume, see EnableVolumeIO in the Amazon Elastic Compute Cloud API Reference.

**Option 3: Delete the Volume If You No Longer Need It**

If you want to remove the volume from your environment, simply delete it. For information about deleting a volume, see Deleting an Amazon EBS Volume (p. 547).

If you have a recent snapshot that backs up the data on the volume, you can create a new volume from the snapshot. For information about creating a volume from a snapshot, see Restoring an Amazon EBS Volume from a Snapshot (p. 528).

**Working with the AutoEnableIO Volume Attribute**

When Amazon EBS determines that a volume’s data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure. If the consistency of a particular volume is not a concern, and you prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the AutoEnableIO volume attribute, I/O between the volume and the instance is automatically reenabled and the volume’s status check will pass. In addition, you’ll see an event that lets you know that the volume
was in a potentially inconsistent state, but that its I/O was automatically enabled. When this event occurs, you should check the volume's consistency and replace it if necessary. For more information, see Monitoring Volume Events (p. 541).

This section explains how to view and modify the AutoEnableIO attribute of a volume using the Amazon EC2 console, the command line interface, or the API.

**To view the AutoEnableIO attribute of a volume in the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Volumes.
3. Select the volume.
4. In the lower pane, click the Status Checks tab.
5. In the Status Checks tab, Auto-Enable IO displays the current setting for your volume, either Enabled or Disabled.

![Image of Volume Status](image)

**To modify the AutoEnableIO attribute of a volume in the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click Volumes.
3. Select the volume.
4. At the top of the Volumes page, click Actions.
5. Click Change Auto-Enable IO Setting.
6. In the Change Auto-Enable IO Setting dialog box, select the Auto-Enable Volume IO option to automatically enable I/O for an impaired volume. To disable the feature, clear the option.
7. Click **Save**.

Alternatively, instead of completing steps 4-6 in the previous procedure, go to the **Status Checks** tab and click **Edit**.

**To view or modify the AutoEnableIO attribute of a volume with the command line**

You can use one of the following commands to view the AutoEnableIO attribute of your Amazon EBS volumes. For more information about these command line interfaces, see [Accessing Amazon EC2](p. 3).

- `describe-volume-attribute` (AWS CLI)
- `ec2-describe-volume-attribute` (Amazon EC2 CLI)
- `Get-EC2VolumeAttribute` (AWS Tools for Windows PowerShell)

To modify the AutoEnableIO attribute of a volume, you can use one of the commands below.

- `modify-volume-attribute` (AWS CLI)
- `ec2-modify-volume-attribute` (Amazon EC2 CLI)
- `Edit-EC2VolumeAttribute` (AWS Tools for Windows PowerShell)

**Detaching an Amazon EBS Volume from an Instance**

You can detach an Amazon EBS volume from an instance explicitly or by terminating the instance. However, a volume must be unmounted inside the instance before being detached. Failure to do so results in the volume being stuck in the busy state while it is trying to detach, which could possibly damage the file system or the data it contains. You can reattach a volume that you detached (without unmounting it), but it may not get the same mount point and the data on the volume might be out of sync if there were writes to the volume in progress when it was detached.

**Note**
If an Amazon EBS volume is the root device of an instance, it cannot be detached unless the instance is in the stopped state.
If the root volume is detached from an instance with an AWS Marketplace product code, then the AWS Marketplace product codes from that volume are no longer associated with the instance.

**Important**
After you detach a volume, you are still charged for volume storage as long as the storage amount exceeds the limit of the Free Usage Tier. You must delete a volume to avoid incurring further charges. For more information, see [Deleting an Amazon EBS Volume](p. 547).

This example unmounts the volume and then explicitly detaches it from the instance. This is useful when you want to terminate an instance or attach a volume to a different instance. To verify that the volume is no longer attached to the instance, see [Viewing Volume Information](p. 536).

**To detach an Amazon EBS volume using the console**

1. First, unmount the volume.
For Linux/Unix, use the following command to unmount the /dev/sdh device.

```
# umount -d /dev/sdh
```

For Windows, open Disk Management, right-click the volume to unmount, and select Change Drive Letter and Path. Then, select the mount point to remove and click Remove.

2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. Click Volumes in the navigation pane.

The console displays a list of current volumes.

4. Select a volume and click Detach Volume.

A confirmation dialog box appears.

5. Click Yes, Detach.

The volume is detached from the instance.

**Caution**
If your volume stays in the detaching state, you can force the detachment by clicking Force Detach. Forcing the detachment can lead to data loss or a corrupted file system. Use this option only as a last resort to detach a volume from a failed instance, or if you are detaching a volume with the intention of deleting it. The instance doesn't get an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures.

If you've tried to force the volume to detach multiple times over several minutes and it stays in the detaching state, you can post a request for help to the Amazon EC2 forum. To help expedite a resolution, include the volume ID and describe the steps that you've already taken.

**To detach an Amazon EBS volume from an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `detach-volume` (AWS CLI)
- `ec2-detach-volume` (Amazon EC2 CLI)
- `Dismount-EC2Volume` (AWS Tools for Windows PowerShell)

**Deleting an Amazon EBS Volume**

After you no longer need a volume, you can delete it. After deletion, its data is gone and the volume can't be attached to any instance. However, before deletion, you can store a snapshot of the volume, which you can use to recreate the volume later.

This section describes how to delete a volume.

**To delete a volume using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Volumes in the navigation pane.

The console displays a list of current volumes.

3. Select a volume and click Delete Volume.

A confirmation dialog box appears.
4. Click Yes, Delete.

    The volume is deleted.

To delete an Amazon EBS volume using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `delete-volume` (AWS CLI)
- `ec2-delete-volume` (Amazon EC2 CLI)
- `Remove-EC2Volume` (AWS Tools for Windows PowerShell)

Expanding the Storage Space of a Volume

Sometimes, it is necessary for you to increase the storage space of an existing volume without losing the data that is on the volume. This topic explains how to expand the storage space of an Amazon EBS volume by migrating your data to a larger volume, and then extending the file system on the volume to recognize the newly-available space. After you verify that your new volume is working properly, you may delete the old volume.

Topics

- Migrating Your Data to a Larger Volume (p. 548)
- Extending a Linux File System (p. 550)
- Extending a Windows File System (p. 552)
- Deleting the Old Volume (p. 554)

Migrating Your Data to a Larger Volume

To migrate your data to a larger Amazon EBS volume

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Ensure that the instance's Shutdown Behavior value is set to Stop and not Terminate. If it is already set to Stop, go on to step 3.

   a. In the navigation pane, click Instances, right-click on the instance to check, and select Change Shutdown Behavior.

   b. If the Shutdown behavior is set to Terminate, select Stop from the list and click Apply.

If the Shutdown behavior is set to Stop, click Cancel.
3. Stop the instance. For more information about how to stop an instance, see Stopping and Starting Your Instances (p. 320).

4. Create a snapshot of the volume to expand.
   a. In the navigation pane, click Volumes, right-click on the volume to be expanded, and select Create Snapshot.
   b. Enter a Name and Description for the snapshot, and click Yes, Create.

5. Create a new volume from the snapshot.
   a. In the navigation pane, click Snapshots.
   b. When the status of the snapshot that you just created is set to completed, select the snapshot and click Create Volume.
      Note
      It can take several minutes for the snapshot to complete.
   c. In the Create Volume dialog box, select the desired volume type, enter the new size for the volume, set the Availability Zone to the same Availability Zone as the instance, and click Yes, Create.

6. Detach the old volume.
   a. In the navigation pane, click Volumes, select the old volume from the list of volumes, and make note of the value of device name in Attachment information. The attachment information value takes the following form:

   "instance information:device name"

   b. Right-click the old volume and select Detach Volume.
   c. In the Detach Volume dialog box, click Yes, Detach. It may take several minutes for the volume to be detached.

7. Attach the newly expanded volume
   a. In the navigation pane, click Volumes, select the new volume from the list of volumes, right-click the new volume, and select Attach Volume.
   b. Start typing the name or ID of the instance in the Instance field, select the instance, enter the same device name retrieved in Step 6.a (p. 549), and click Yes, Attach.

8. Restart the instance.
   a. In the navigation pane, click Instances, right-click the instance, and select Start.
   b. In the Start Instances dialog box, select Yes, Start. If the instance fails to start, and the volume being expanded is a root volume, verify that you attached the expanded volume using the same device name as the original volume (root volumes must be attached as /dev/sda1).

   Important
   Only EC2-VPC instances with Elastic IP addresses retain their public IP address when they are stopped. If your instance is running in EC2-Classic, the EIP address is disassociated when the instance is stopped, and you must re-associate the EIP after restarting the instance. For more information, see Elastic IP Addresses (EIP) (p. 498). If your instance is not using an EIP, then you need to retrieve your new public DNS
name for your instance from the Instances page of the Amazon EC2 console to connect to it.

After the instance has started, you can check the file system size to see if your instance recognizes the larger volume space. On Linux, use the `df -h` command to check the file system size.

```
[ec2-user ~]$ df -h
Filesystem             Size  Used Avail Use% Mounted on
/dev/xvda1             7.9G  943M  6.9G  12% /
tmpfs                 1.9G     0  1.9G   0% /dev/shm
```

If the value in the `Size` column does not indicate your newly-expanded volume size, you need to extend the file system on your device so that your instance can use the new space. This procedure varies depending on the operating system running on the instance. For information about how to do this on different operating systems, see the following topics:

- Extending a Linux File System (p. 550)
- Extending a Windows File System (p. 552)

**Extending a Linux File System**

In Linux, you use a file system-specific command to resize the file system to the larger size of the new volume. This command works even if the volume you wish to extend is the root volume. For `ext2`, `ext3`, and `ext4` file systems, this command is `resize2fs`. For XFS file systems, this command is `xfs_growfs`. For other file systems, refer to the specific documentation for those file systems for instructions on extending them.

If you are unsure of which file system you are using, you can use the `file -s` command to list the file system data for a device. The following example shows a Linux `ext4` file system and an SGI XFS file system.

```
[ec2-user ~]$ sudo file -s /dev/xvd*
/dev/xvdal: Linux rev 1.0 ext4 filesystem data ...
/dev/xvdf: SGI XFS filesystem data ...
```

**Note**

If the volume you are extending has been partitioned, you need to increase the size of the partition before you can resize the file system. For more information, see Expanding a Linux Partition (p. 554).

**To check if your volume partition needs resizing**

- Use the `lsblk` command to list the block devices attached to your instance. The example below shows three volumes: `/dev/xvda`, `/dev/xvdb`, and `/dev/xvdf`.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
xvda   202:0    0   30G 0 disk
  xvda1 202:1    0   30G 0 part /
xvdb   202:16   0   30G 0 disk /mnt
xvdf   202:80   0   35G 0 disk
  xvdf1 202:81   0   8G  0 part
```
The root volume, /dev/xvda1, is a partition on /dev/xvda. Notice that they are both 30 GB in size. In this case, the partition occupies all of the room on the device, so it does not need resizing.

The volume /dev/xvdb is not partitioned at all, so it does not need resizing.

However, /dev/xvdf1 is an 8 GB partition on a 35 GB device and there are no other partitions on the volume. In this case, the partition must be resized in order to use the remaining space on the volume. For more information, see Expanding a Linux Partition (p. 554). After you resize the partition, you can follow the next procedure to extend the file system to occupy all of the space on the partition.

To extend a Linux file system

1. Log in to your Linux instance using an SSH client. For more information about connecting to a Linux instance, see Connecting to Your Linux/Unix Instances Using SSH (p. 308).

2. Use the `df -h` command to report the existing file system disk space usage. In this example, the /dev/xvda1 device has already been expanded to 70 GB, but the ext4 file system only sees the original 8 GB size, and the /dev/xvdf device has been expanded to 100 GB, but the XFS file system only sees the original 1 GB size.

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Size</th>
<th>Used</th>
<th>Avail</th>
<th>Use%</th>
<th>Mounted on</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/xvda1</td>
<td>7.9G</td>
<td>943M</td>
<td>6.9G</td>
<td>12%</td>
<td>/</td>
</tr>
<tr>
<td>tmpfs</td>
<td>1.9G</td>
<td>0</td>
<td>1.9G</td>
<td>0%</td>
<td>/dev/shm</td>
</tr>
<tr>
<td>/dev/xvdf</td>
<td>1014M</td>
<td>33M</td>
<td>982M</td>
<td>4%</td>
<td>/mnt</td>
</tr>
</tbody>
</table>

3. Use the file system-specific command to resize the file system to the new size of the volume. For a Linux ext2, ext3, or ext4 file system, use the following command, substituting the device name that you want to extend.

   [ec2-user ~]$ sudo resize2fs /dev/xvda1
   resize2fs 1.42.3 (14-May-2012)
   Filesystem at /dev/xvda1 is mounted on /; on-line resizing required
   old_desc_blocks = 1, new_desc_blocks = 5
   Performing an on-line resize of /dev/xvda1 to 18350080 (4k) blocks.
   The filesystem on /dev/xvda1 is now 18350080 blocks long.

   For an XFS file system, use the following command, substituting the mount point of the file system (XFS file systems must be mounted to resize them).

   [ec2-user ~]$ sudo xfs_growfs -d /mnt
   xfs_growfs 1.4.3 (2012-05-18)
  meta-data=/dev/xvdf isize=256 agcount=4, agsize=65536 blks
   =         secsz=512 attr=2
   data      =      bsize=4096 blocks=262144, imaxpct=25
   =          sunit=0      swidth=0 blks
   naming    =version 2 bsize=4096 ascii-ci=0
   =          isize=256
   log        =internal bsize=4096 blocks=2560, version=2
   =          sectsz=512
   =          sunit=0      blks, lazy-count=1
   realtime  =none    extsz=4096 blocks=0, rtextents=0
   data blocks changed from 262144 to 26214400

   Note
   If you receive an xfsctl failed: Cannot allocate memory error, you may need to update the Linux kernel on your instance. For more information, refer to your specific operating system documentation.
4. Use the `df -h` command to report the existing file system disk space usage, which should now show the full 70 GB on the ext4 file system and 100 GB on the XFS file system.

```
# df -h
Filesystem            Size  Used Avail Use% Mounted on
/dev/xvda1             69G  951M   68G   2% /
tmpfs                  1.9G     0  1.9G   0% /dev/shm
/dev/xvdf             100G   45M  100G   1% /mnt
```

**Extending a Windows File System**

In Windows, you use the Disk Management utility to extend the disk size to the new size of the volume.

**To extend a Windows file system**

1. Log in to your Windows instance using Remote Desktop.
   • Windows Server 2008: On the taskbar, click **Start**, and then click **Run**.
3. Type `diskmgmt.msc` and press **Enter**. The **Disk Management** utility opens.

   ![Disk Management](image)

4. Right-click the expanded drive and select **Extend Volume**.
5. In the Extend Volume Wizard, click Next, then set the Select the amount of space in MB field to the number of megabytes by which to extend the volume. Normally, you set this to the maximum available space. Complete the wizard.
Deleting the Old Volume

After the new volume has been attached and extended in the instance, you can delete the old volume if it is no longer needed.

To delete the old volume

1. In the Amazon EC2 console, click Volumes in the navigation pane.
2. Right-click the old volume and select Delete Volume.
3. In the Delete Volume dialog box, click Yes, Delete.

Expanding a Linux Partition

Some Amazon EC2 root volumes and volumes that are restored from snapshots contain a partition that actually holds the file system and the data. If you think of a volume as a container, a partition is another container inside the volume, and the data resides on the partition. Growing the volume size does not grow the partition; to take advantage of a larger volume, the partition must be expanded to the new size.

Note

Not all volumes restored from snapshots are partitioned, and this procedure may not apply to your volume. You may just need to resize the file system on your volume to make all of the space available. If you are not sure if your volume has a partition that needs resizing, see To check if your volume partition needs resizing (p. 550) for more information.

If the partition you want to expand is not the root partition, then you can simply unmount it and resize the partition from the instance itself. If the partition you need to resize is the root partition, the process becomes
more complicated because you cannot unmount the root partition of a running instance. You have to perform the following procedures on another instance, which is referred to as a secondary instance.

**Important**
The following procedures were written for and tested on Amazon Linux. Other distributions with different tool sets and tool versions may behave differently.

### To prepare a Linux root partition for expansion

There are several steps that you need to take to expand the root partition of an instance. If the partition you need to expand is not the root partition, then this procedure is not necessary.

1. If your primary instance is running, stop it. You cannot perform the rest of this procedure on a running instance. For more information, see Stop and Start Your Instance (p. 319).
2. Take a snapshot of your volume. It can be easy to corrupt or lose your data in the following procedures. If you have a fresh snapshot, you can always start over in case of a mistake and your data will still be safe. For more information, see Creating an Amazon EBS Snapshot (p. 559).
3. Record the device name that the volume is attached to. You can find this information on the Root device field of the instance’s details pane. The value is likely /dev/sda1 or /dev/xvda.
4. Detach the volume from the primary instance. For more information, see Detaching an Amazon EBS Volume from an Instance (p. 546).
5. Attach the volume to another (secondary) instance in the same Availability Zone. For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529). If you do not already have a secondary instance, you will need to launch one. For more information, see Launching an Instance (p. 300).
6. Log in to the secondary instance with SSH. For more information, see Connect to Your Instance (p. 308). Continue with the next procedure.

### To expand a Linux partition

If the partition you need to expand is the root partition, be sure to follow the previous procedure first.

1. Identify the device that contains the partition that you want to expand. Use the `lsblk` command to list all devices and partitions attached to the instance.

   ```bash
   [ec2-user ~]$ lsblk
   NAME    MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
   xvdf    202:80   0  100G  0 disk
   xvdf1 202:81   0    8G  0 part /mnt
   xvda1   202:1    0   30G  0 disk /
   
   In this example, the `xvdf` device has 100 GB of available storage and it contains an 8 GB partition.
   ```

2. Unmount the partition if it is mounted. Run the `umount` command with the value of MOUNTPOINT from the `lsblk` command. In this example, the MOUNTPOINT value for the partition is `/mnt`.

   ```bash
   [ec2-user ~]$ sudo umount /mnt
   
   Take a snapshot of your volume (unless you just took one in the previous procedure). It can be easy to corrupt or lose your data in the following procedures. If you have a fresh snapshot, you can always start over in case of a mistake and your data will still be safe. For more information, see Creating an Amazon EBS Snapshot (p. 559).

3. Run the `parted` command on the device (and not the partition on the device). Remember to add the `/dev/` prefix to the name that `lsblk` outputs.
5. Change the `parted` units of measure to sectors.

(parted) `unit s`

6. Run the `print` command to list the partitions on the device. For certain partition table types, you might be prompted to repair the partition table for the larger volume size.

(parted) `print`

a. (Optional) If you receive the following message, enter ‘Fix’ to move the backup GPT table to the end of the disk.

```
Error: The backup GPT table is not at the end of the disk, as it should be. This might mean that another operating system believes the disk is smaller. Fix, by moving the backup to the end (and removing the old backup)?
Fix/Ignore/Cancel? Fix
```

b. (Optional) If you receive the following message, enter “Fix” again to make the space on the drive available.

```
Warning: Not all of the space available to /dev/xvdf appears to be used, you can fix the GPT to use all of the space (an extra 46137344 blocks) or continue with the current setting?
Fix/Ignore? Fix
```

7. Examine the output for the total size of the disk, the partition table type, the number of the partition, the start point of the partition, and the name of the partition. For gpt partition tables, note the name of the partition; for msdos partition tables, note the Type field (primary or extended). These values are used in the upcoming steps.

The following is a gpt partition table example.

```
Model: Xen Virtual Block Device (xvd)
Disk /dev/xvdf: 209715200s
Sector size (logical/physical): 512B/512B
Partition Table: gpt

Number  Start  End        Size       File system  Name                 Flags
128     2048s  4095s      2048s                   BIOS Boot Partition
        bios_grub
1       4096s  16777182s  16773087s  ext4           Linux
```

The following is an msdos partition table example.
8. Delete the partition entry for the partition using the number (1) from the previous step.

```
(parted) rm 1
```

9. Create a new partition that extends to the end of the volume.

(For the gpt partition table example) Note the start point and name of partition 1 above. For the gpt example, there is a start point of 4096s, and the name Linux. Run the `mkpart` command with the start point of partition 1, the name, and 100% to use all of the available space.

```
(parted) mkpart Linux 4096s 100%
```

(For the msdos partition table example) Note the start point and the partition type of partition 1 above. For the msdos example, there is a start point of 2048s and a partition type of `primary`. Run the `mkpart` command with a primary partition type, the start point of partition 1, and 100% to use all of the available space.

```
(parted) mkpart primary 2048s 100%
```

10. Run the `print` command again to verify your partition.

(For the gpt partition table example)

```
(parted) print
Model: Xen Virtual Block Device (xvd)
Disk /dev/xvdf: 209715200s
Sector size (logical/physical): 512B/512B
Partition Table: gpt
Number  Start  End         Size        File system  Name  Flags
        128     2048s  4095s       2048s                    BIOS Boot Partition           bios_grub
        1      4096s  209713151s  209709056s  ext4         Linux
```

(For the msdos partition table example)

```
(parted) print
Model: Xen Virtual Block Device (xvd)
Disk /dev/xvdg: 104857600s
Sector size (logical/physical): 512B/512B
Partition Table: msdos
Number  Start  End        Size       Type     File system  Flags
1      2048s  35649535s  35647488s  primary  ext3
```

Amazon Elastic Compute Cloud User Guide
EBS Volumes
11. Run the `quit` command to exit `parted`.

```
(parted) quit
```

**Note**
Because you removed a partition and added a partition, `parted` may warn that you may need to update `/etc/fstab`. This is only required if the partition number changes.

12. Check the file system to make sure there are no errors (this is required before you may extend the file system).

```
[ec2-user ~]$ sudo e2fsck -f /dev/xvdf1
```

```
e2fsck 1.42.3 (14-May-2012)
Pass 1: Checking inodes, blocks, and sizes
Pass 2: Checking directory structure
Pass 3: Checking directory connectivity
Pass 4: Checking reference counts
Pass 5: Checking group summary information
/: 31568/524288 files (0.4% non-contiguous), 266685/2096635 blocks
```

13. The next steps differ depending on whether the expanded partition belongs on the current instance or if it is the root partition for another instance.

- If this partition belongs on the current instance, remount the partition at the `MOUNTPOINT` identified in Step 2 (p. 555).

```
[ec2-user ~]$ sudo mount /dev/xvdf1 /mnt
```

After you have mounted the partition, extend the file system to use the newly available space by following the procedures in Extending a Linux File System (p. 550).

- If this volume is the root partition for another instance, proceed to the next procedure.

**To return an expanded root partition to its original instance**

1. Detach the expanded partition from its secondary instance. For more information, see Detaching an Amazon EBS Volume from an Instance (p. 546).

2. Reattach the volume to the primary instance using the device name that you identified in Step 3 (p. 555) of the preparation procedure (p. 555). For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529).

3. Start the primary instance. For more information, see Stop and Start Your Instance (p. 319).

4. (Optional) If you launched a secondary instance for the sole purpose of expanding the partition, you can terminate the instance to stop incurring charges. For more information, see Terminate Your Instance (p. 325).

5. Connect to your primary instance and extend the file system to use the newly available space by following the procedures in Extending a Linux File System (p. 550).
After you are finished with this expanding the file system, you can create an AMI from the instance that you can use to launch new instances with the desired partition size. For more information, see Amazon Machine Images (AMI) (p. 48).

Amazon EBS Snapshots

An Amazon EBS snapshot is a point-in-time backup copy of an Amazon EBS volume that is stored in Amazon S3. Snapshots are incremental backups, which means that only the blocks on the device that have changed after your most recent snapshot are saved. When you delete a snapshot, only the data exclusive to that snapshot is removed. Active snapshots contain all of the information needed to restore your data (from the time the snapshot was taken) to a new Amazon EBS volume.

If you are dealing with snapshots of sensitive data, you should consider encrypting your data manually before taking the snapshot.

Topics

- Creating an Amazon EBS Snapshot (p. 559)
- Deleting an Amazon EBS Snapshot (p. 560)
- Copying an Amazon EBS Snapshot (p. 561)
- Viewing Snapshot Information (p. 562)
- Sharing Snapshots (p. 563)

When you create a new Amazon EBS volume, you may create it based on an existing snapshot; the new volume begins as an exact replica of the original volume that was used to create the snapshot. New volumes created from existing Amazon S3 snapshots load lazily in the background, so you can begin using them right away. If your instance accesses a piece of data that hasn't yet been loaded, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume's data in the background. For more information about creating snapshots, see Creating an Amazon EBS Snapshot (p. 559).

You can share your snapshots with specific individuals, or make them public to share them with the entire AWS community. Users with access to your snapshots can create their own Amazon EBS volumes from your snapshot, but your snapshots remain completely intact. For more information about how to share snapshots, see Sharing Snapshots (p. 563).

Amazon EBS snapshots are constrained to the region in which they are created. Once you have created a snapshot of an Amazon EBS volume, you can use it to create new volumes in the same region. For more information, see Restoring an Amazon EBS Volume from a Snapshot (p. 528). You may also copy snapshots across AWS regions, making it easier to leverage multiple AWS regions for geographical expansion, data center migration and disaster recovery. You may copy any accessible snapshots that are in the “available” status. For more information, see Copying an Amazon EBS Snapshot (p. 561).

Creating an Amazon EBS Snapshot

After writing data to an Amazon EBS volume, you can periodically create a snapshot of the volume to use as a baseline for new volumes or for data backup. If you make periodic snapshots of a volume, the snapshots are incremental so that only the blocks on the device that have changed after your last snapshot are saved in the new snapshot. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to restore the volume.

Snapshots occur asynchronously and the status of the snapshot is pending until the snapshot is complete.

By default, only you can launch volumes from snapshots that you own. However, you can choose to share your snapshots with specific AWS accounts or make them public. For more information, see Sharing Snapshots (p. 563).
When a snapshot is created, any AWS Marketplace product codes from the volume are propagated to the snapshot.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your Amazon EBS volume at the time the snapshot command is issued. This may exclude any data that has been cached by any applications or the operating system. If you can pause any file writes to the volume long enough to take a snapshot, your snapshot should be complete. However, if you can’t pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You may remount and use your volume while the snapshot status is pending.

To create a snapshot for Amazon EBS volumes that serve as root devices, you should stop the instance before taking the snapshot.

To unmount the volume in Linux/Unix, use the following command:

```
umount -d device_name
```

Where `device_name` is the device name (for example, /dev/sdh).

To unmount the volume in Windows, open Disk Management, right-click the volume to unmount, and select Change Drive Letter and Path. Select the mount point to remove, and then click Remove.

**To create a snapshot using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Snapshots in the navigation pane.
   The console displays a list of current snapshots.
3. Click Create Snapshot.
   The Create Snapshot dialog box appears.
4. Select the volume to create a snapshot for and click Create.
   Amazon EC2 begins creating the snapshot.

**To create a snapshot using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- `create-snapshot` (AWS CLI)
- `ec2-create-snapshot` (Amazon EC2 CLI)
- `New-EC2Snapshot` (AWS Tools for Windows PowerShell)

**Deleting an Amazon EBS Snapshot**

This section describes how to delete a snapshot.

**Note**

- If you make periodic snapshots of a volume, the snapshots are incremental so that only the blocks on the device that have changed since your last snapshot are saved in the new snapshot. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to restore the volume.
• You cannot delete a snapshot of the root device of an Amazon EBS volume used by a registered AMI. You must first deregister the AMI before you can delete the snapshot. For more information, see Deregistering Your AMI (p. 83).

To delete a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Snapshots in the navigation pane.
   
The console displays a list of current snapshots.
3. Select a snapshot, and select Delete from the Actions list.
4. Click Yes, Delete.
   
The snapshot is deleted.

To delete a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- delete-snapshot (AWS CLI)
- ec2-delete-snapshot (Amazon EC2 CLI)
- Remove-EC2Snapshot (AWS Tools for Windows PowerShell)

Copying an Amazon EBS Snapshot

Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances. With Amazon EBS, you can create point-in-time snapshots of volumes and store them on Amazon Simple Storage Service (Amazon S3). After you've stored a snapshot in Amazon S3, you can copy it from one AWS region to another, or within the same region, using the Amazon EC2 console, Amazon EC2 CLI, or the API. You can use snapshot copies to create backups of data, to create new Amazon EBS volumes, or to create Amazon Machine Images (AMIs).

You can have up to five snapshot copy requests in progress to a single destination per account. You can copy any accessible Amazon EBS snapshots that have “completed” status, including shared snapshots and snapshots that you've created. You can also copy AWS Marketplace, VM Import/Export, and AWS Storage Gateway snapshots, but you must verify that the snapshot is supported in the destination region.

The first snapshot copy of a volume is always a full copy. Each subsequent snapshot copy is incremental, meaning that only the blocks on the volume that have changed since your last snapshot copy to the same destination are transferred. Incremental snapshots make the copy process faster. Support for incremental snapshots is specific to a region pair. For example, if you copy a snapshot from the US East (Northern Virginia) Region to the US West (Oregon) Region, the first snapshot copy of the volume is a full copy. However, subsequent snapshot copies of the same volume transferred between the same regions are incremental. A snapshot copy can only be done incrementally as long as there is one full copy of the same volume available in the destination region.

Note
To copy an Amazon Relational Database Service (Amazon RDS) snapshot, see Copying a DB Snapshot in the Amazon Relational Database Service User Guide.

When you copy a snapshot, you are only charged for the data transfer and storage used to copy the snapshot data across regions and to store the copied snapshot in the destination region. You are not charged if the snapshot copy fails. However, if you cancel a snapshot copy that is not yet complete, or
delete the source snapshot while the copy is in progress, you are charged for the bandwidth of the data transferred. The snapshot is copied across regions using the secure Amazon S3 Copy and the snapshot copy receives a snapshot ID that's different from the original snapshot's ID.

You can use a copy of an Amazon EBS snapshot in the following ways:

- **Geographic Expansion**: You can launch your applications in a new region.
- **Migration**: You can migrate an application to a new region, to enable better availability and minimize cost.
- **Disaster Recovery**: You can back up your data and logs across different geographical locations at regular intervals. In case of disaster, you can restore your applications using point-in-time backups stored in the secondary region. This minimizes data loss and recovery time.

The Amazon EC2 console, Amazon EC2 CLI, and the API are designed to provide an intuitive customer experience. We use the push model in the console design to minimize user clicks for the Amazon EBS snapshot use cases discussed earlier. You can easily initiate a copy from the console by starting with the source region. We use a pull model in the Amazon EC2 CLI and the API, because these experiences factor in how customers use automation. You only need to know the source snapshot ID and source region to initiate the copy using the Amazon EC2 CLI or API.

**To copy a snapshot using the Amazon EC2 console**

You can create a copy of an Amazon EBS snapshot using the Amazon EC2 console.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click **Snapshots**.
3. Select the snapshot to copy, and then select **Copy** from the **Actions** list.
4. In the **Copy Snapshot** dialog box, update the following as necessary:
   - **Destination region**: Select the region where you want to write the copy of the snapshot.
   - **Description**: By default, the description includes information about the source snapshot so that you can identify a copy from the original. You can change this description as necessary.
5. Click **Yes, Copy**.
6. In the **Copy Snapshot** confirmation dialog box, you can click **Snapshots** to go to the **Snapshots** page in the region specified, or click **Close**.

To view the progress of the copy process later, switch the Amazon EC2 console to the destination region, and then refresh the **Snapshots** page. Copies in progress are listed at the top of the page.

**To copy a snapshot using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Accessing Amazon EC2](p. 3).

- **copy-snapshot** (AWS CLI)
- **ec2-copy-snapshot** (Amazon EC2 CLI)
- **Copy-EC2Snapshot** (AWS Tools for Windows PowerShell)

**Viewing Snapshot Information**

This section describes how to view descriptive information about the snapshots that you have created.
To view descriptive snapshot information in the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Snapshots in the navigation pane.
   The console displays a list of all snapshots to which you have access, and their status.
3. To reduce the list, select an option from the Filter list. For example, to view only your snapshots, select Owned By Me.
   The console displays a new list of snapshots.
4. To view more information about a snapshot, select it.
   Information about the snapshot appears in the lower pane.

To view descriptive snapshot information using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- describe-snapshots (AWS CLI)
- ec2-describe-snapshots (Amazon EC2 CLI)
- Get-EC2Snapshot (AWS Tools for Windows PowerShell)

Sharing Snapshots

This section describes how to share your Amazon EBS snapshots with your co-workers or others in the AWS community by modifying the permissions of the snapshot.

Users that you have authorized can quickly use your Amazon EBS shared snapshots as the basis for creating their own Amazon EBS volumes. If you choose, you can also make your data available publicly to all AWS users. Users to whom you have granted access can create their own Amazon EBS volumes based on your snapshot and your original snapshot remains intact.

**Note**
Snapshots are constrained to the region in which they are created. If you would like to share a snapshot with another region, you need to copy the snapshot to that region. For more information about copying snapshots, see Copying an Amazon EBS Snapshot (p. 561).

**Important**
When you share a snapshot (whether by sharing it with another AWS account or making it public to all), you are giving others access to all the data on your snapshot. Share snapshots only with people with whom you want to share all your snapshot data.

To modify snapshot permissions in the console

This procedure will help you to share your snapshots.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Click Snapshots in the navigation pane.
   The console displays a list of current snapshots and their status.
3. Select a snapshot and select Modify Snapshot Permissions from the Actions list.
4. Choose whether to make the snapshot public or to share it with select AWS accounts:
   **Important**
   Making your snapshot public shares all snapshot data with everyone. Snapshots with AWS Marketplace product codes cannot be made public.
To make the snapshot public, select Public.
To expose the snapshot only to specific AWS accounts, select Private, enter the ID of the AWS account (without hyphens) in the AWS Account Number field, and click Add Permission. Repeat until you’ve added all the required AWS accounts.

Click Save when you’re done.

To view and modify snapshot permissions using the command line

To view the createVolumePermission attribute of a snapshot, you can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- describe-snapshot-attribute (AWS CLI)
- ec2-describe-snapshot-attribute (Amazon EC2 CLI)
- Get-EC2SnapshotAttribute (AWS Tools for Windows PowerShell)

To modify the createVolumePermission attribute of a snapshot, you can use one of the following commands.

- modify-snapshot-attribute (AWS CLI)
- ec2-modify-snapshot-attribute (Amazon EC2 CLI)
- Edit-EC2SnapshotAttribute (AWS Tools for Windows PowerShell)

Amazon EBS Volume Performance

Several factors can affect the performance of Amazon EBS volumes, such as instance configuration, I/O characteristics, workload demand, and storage configuration. After you learn the basics of working with EBS volumes, it’s a good idea to look at the I/O performance you require and at your options for increasing EBS performance to meet those requirements.

Topics

- Amazon EBS Performance Tips (p. 564)
- Amazon EC2 Instance Configuration (p. 565)
- I/O Characteristics (p. 566)
- Workload Demand (p. 567)
- Pre-Warming Amazon EBS Volumes (p. 568)
- RAID Configuration (p. 572)
- Benchmark Volumes (p. 577)

Amazon EBS Performance Tips

- When you consider the performance requirements for your EBS storage application, it is important to start with an EC2 configuration that is optimized for EBS and that can handle the bandwidth that your application storage system requires. For more information, see Amazon EC2 Instance Configuration (p. 565).
- When you measure the performance of your EBS volumes, especially with provisioned IOPS volumes, it is important to understand the units of measure involved and how performance is calculated. For more information, see I/O Characteristics (p. 566).
There is a relationship between the maximum performance of your EBS volumes, the amount of I/O you are driving to them, and the amount of time it takes for each transaction to complete. Each of these factors (performance, I/O, and time) affects the others, and different applications are more sensitive to one factor or another. For more information, see Workload Demand (p. 567).

There is a 5 to 50 percent reduction in IOPS when you first access each block of data on a newly created or restored EBS volume. You can avoid this performance hit by accessing each block in advance. For more information, see Pre-Warming Amazon EBS Volumes (p. 568).

Some instance types can handle more IOPS than you can provision for a single volume. You can join multiple provisioned IOPS volumes together in a RAID 0 configuration to use the available bandwidth for these instances. You can also provide redundancy for your volumes with a RAID 1 (mirrored) configuration. For more information, see RAID Configuration (p. 572).

You can benchmark your storage and compute configuration to make sure you achieve the level of performance you expect to see before taking your application live. For more information, see Benchmark Volumes (p. 577).

Amazon Web Services provides performance metrics for EBS that you can analyze and view with Amazon CloudWatch and status checks that you can use to monitor the health of your volumes. For more information, see Monitoring the Status of Your Volumes (p. 536).

Frequent snapshots provide a higher level of data durability, but they may slightly degrade the performance of your application while the snapshot is in progress. This trade off becomes critical when you have data that changes rapidly. Whenever possible, plan for snapshots to occur during off-peak times in order to minimize workload impact. For more information, see Amazon EBS Snapshots (p. 559).

Amazon EC2 Instance Configuration

When you plan and configure EBS volumes for your application, it is important to consider the configuration of the instances that you will attach the volumes to. In order to get the most performance out of your EBS volumes, you should attach them to an instance with enough bandwidth to support your volumes, such as an EBS-optimized instance or an instance with 10 Gigabit network connectivity. This is especially important when you use provisioned IOPS volumes, or when you stripe multiple volumes together in a RAID configuration.

Use EBS-Optimized or 10 Gigabit Network Instances

Any performance-sensitive workloads that require minimal variability and dedicated EC2 to EBS traffic, such as production databases or business applications, should use provisioned IOPS volumes that are attached to an EBS-optimized instance or an instance with 10 Gigabit network connectivity. EC2 instances that do not meet this criteria offer no guarantee of network resources. The only way to ensure sustained reliable network bandwidth between your EC2 instance and your EBS volumes is to launch the EC2 instance as EBS-optimized or choose an instance type with 10 Gigabit network connectivity. To see which instance types include 10 Gigabit network connectivity, see Instance Type Details.

Choose an EC2 Instance with Enough Bandwidth

Launching an instance that is EBS-optimized provides you with a dedicated connection between your EC2 instance and your EBS volume. However, it is still possible to provision EBS volumes that exceed the available bandwidth for certain instance types, especially when multiple volumes are striped in a RAID configuration. The following table shows which instance types are available to be launched as EBS-optimized and the maximum amount of IOPS the instance can support. Be sure to choose an EBS-optimized instance that provides dedicated EBS throughput that exceeds the amount of EBS bandwidth needed for your application; otherwise, the EBS to EC2 connection will become a performance bottleneck.

The m1.large instance has a maximum 16 KB IOPS value of 4,000, but unless this instance type is launched as EBS-optimized, that value is an absolute best-case scenario and is not guaranteed; to consistently achieve 4,000 16 KB IOPS, you must launch this instance as EBS-optimized. However, if two 4,000 provisioned IOPS EBS volumes are attached to an EBS-optimized m1.large instance in a RAID configuration, the EC2 to EBS connection bandwidth limit will prevent these volumes from providing the maximum IOPS that were provisioned for them. In this case, we must use an EBS-optimized EC2 instance that supports 8,000 16 KB IOPS, such as the m1.xlarge instance type.

Instance types with 10 Gigabit network connectivity support up to 48,000 16K IOPS. Since the maximum provisioned IOPS value for EBS volumes is 4,000, you would have to use multiple EBS volumes simultaneously to reach the level of I/O performance available to these instance types. To see which instance types include 10 Gigabit network connectivity, see Instance Type Details.

You should use EBS-optimized instances when available to get the full performance benefits of Amazon EBS Provisioned IOPS volumes. For more information, see Amazon EBS-Optimized Instances (p. 114).

**I/O Characteristics**

On a given volume configuration, certain I/O characteristics drive the performance behavior on the back end. Provisioned IOPS volumes deliver consistent performance whether an I/O operation is random or sequential, and also whether an I/O operation is to read or write data. I/O size, however, does make an impact on IOPS because of the way they are measured. In order to fully understand provisioned IOPS...
volumes and how they will perform in your application, it is important to know what IOPS are and how they are measured.

What are IOPS?

IOPS are input/output operations per second. Amazon EBS measures these I/O operations in 16 KB chunks. When you provision a 4,000 IOPS volume and attach it to an EBS-optimized instance that can provide the necessary bandwidth, you can transfer 4,000 16 KB chunks of data per second (for a bandwidth of approximately 62.5 MBs or 500 Mbps).

This configuration could transfer 2,000 32 KB chunks, or 1,000 64 KB chunks of data per second as well, before it reached a bandwidth limit that equals 4000 16 KB I/O operations per second. If your I/O chunks are greater than 16 KB, you may experience a smaller number of IOPS than you provisioned, but the bandwidth you experience should equal the amount that would be used by your provisioned amount of 16 KB IOPS.

For 16 KB or smaller I/O operations, you should see the amount of IOPS that you have provisioned, provided that you are driving enough I/O to keep the drives busy. For smaller I/O operations, you may even see an IOPS value that is higher than what you have provisioned (when measured on the client side), and this is because the client may be coalescing multiple smaller I/O operations into a single 16 KB chunk.

If you are not experiencing the expected IOPS or throughput you have provisioned, ensure that your EC2 bandwidth is not the limiting factor; your instance should be EBS-optimized (or include 10 Gigabit network connectivity) and your instance type EBS dedicated bandwidth should exceed the IOPS you have provisioned. For more information, see Amazon EC2 Instance Configuration (p. 565). Another possible cause for not experiencing the expected IOPS is that you are not driving enough I/O to the EBS volumes. For more information, see Workload Demand (p. 567).

Workload Demand

Workload demand plays an important role in getting the most out of your provisioned IOPS volumes. In order for your volumes to deliver the amount of IOPS that you have provisioned, they need to have enough I/O requests sent to them. There is a relationship between the demand on the volumes, the amount of IOPS that are provisioned for them, and the latency of the request (the amount of time it takes for the I/O operation to complete).

Average Queue Length

The queue length is the number of pending I/O requests for a device. Optimal average queue length will vary for every customer workload, and this value depends on your particular application's sensitivity to IOPS and latency. If your workload is not delivering enough I/O requests to maintain your optimal average queue length, then your volume might not consistently deliver the IOPS that you have provisioned. However, if your workload maintains an average queue length that is higher than your optimal value, then your per-request I/O latency will increase; in this case, you should provision more IOPS for your volume. We recommend that you target an optimal average queue length of 1 for every 200 Provisioned IOPS and tune that value based on your application requirements. For example, a volume with 1000 Provisioned IOPS should target an average queue length of 5.

Note

Per-request I/O latency may increase with higher average queue lengths.

Latency

Latency is the true end-to-end client time of an I/O operation; in other words, when the client sends a IO, how long does it take to get an acknowledgement from the storage subsystem that the IO read or write is complete. If your I/O latency is higher than you require, check your average queue length to make sure that your application is not trying to drive more IOPS than you have provisioned. You can maintain high
IOPS while keeping latency down by maintaining a low average queue length (which is achieved by provisioning more IOPS for your volume).

**Pre-Warming Amazon EBS Volumes**

When you create a new EBS volume or restore a volume from a snapshot, the back-end storage blocks are allocated to you immediately. However, the first time you access a block of storage, it must be either wiped clean (for new volumes) or instantiated from its snapshot (for restored volumes) before you can access the block. This preliminary action takes time and can cause a 5 to 50 percent loss of IOPS for your volume the first time each block is accessed. For most applications, amortizing this cost over the lifetime of the volume is acceptable. Performance is restored after the data is accessed once.

However, you can avoid this performance hit in a production environment by writing to or reading from all of the blocks on your volume before you use it; this process is called pre-warming. Writing to all of the blocks on a volume is preferred, but that is not an option for volumes that were restored from a snapshot, because that would overwrite the restored data. For a completely new volume that was created from scratch, you should write to all blocks before using the volume. For a new volume created from a snapshot, you should read all the blocks that have data before using the volume.

**Pre-warming Amazon EBS Volumes on Linux**

**To Pre-Warm a New Volume on Linux**

For a new volume, use the `dd` command to write to all blocks on a volume. This procedure will write zeroes to all of the blocks on the device and it will prepare the volume for use. Any existing data on the volume will be lost.

1. Attach the newly created volume to your Linux instance.
2. Use the `lsblk` command to list the block devices on your instance.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvdf  202:80   0  30G  0 disk
xvda1 202:1    0   8G  0 disk /
```

Here you can see that the new volume, `/dev/xvdf`, is attached, but not mounted (because there is no path listed under the `MOUNTPOINT` column).

**Important**

If your new volume is mounted, unmount it. Step 4 (p. 568) should not be performed on a mounted device.

3. (Optional) If your volume is mounted, unmount it with the following command.

```
[ec2-user ~]$ sudo umount /dev/xvdf
```

4. Use the `dd` command to write to all of the blocks on the device. The `if` (import file) parameter should be set to one of the Linux virtual devices, such as `/dev/zero`. The `of` (output file) parameter should be set to the drive you wish to warm. The `bs` parameter sets the block size of the write operation; for optimal performance, this should be set to 1 MB.
Note
This step may take several minutes up to several hours, depending on your EC2 instance
bandwidth, the IOPS provisioned for the volume, and the size of the volume.

When the operation is finished, you will see a report of the write operation.

```
[ec2-user ~]$ sudo dd if=/dev/zero of=/dev/xvdf bs=1M
```

Your volume is now ready for use. For more information, see Making an Amazon EBS Volume
Available for Use (p. 532).

**To Pre-Warm a Volume Restored from a Snapshot on Linux**

For volumes that have been restored from snapshots, use the `dd` command to read from (and optionally
write back to) all blocks on a volume. All existing data on the volume will be preserved.

1. Attach the newly restored volume to your Linux instance.
2. Use the `lsblk` command to list the block devices on your instance.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
xvdf  202:80   0  30G  0 disk
xvda1 202:1    0   8G  0 disk /
```

Here you can see that the new volume, /dev/xvdf, is attached, but not mounted (because there
is no path listed under the MOUNTPOINT column).

**Important**
If your new volume is mounted, unmount it. Step 4 (p. 569) should not be performed on a
mounted device.

3. (Optional) If your volume is mounted, unmount it with the following command.

```
[ec2-user ~]$ sudo umount /dev/xvdf
```

4. Use the `dd` command to read all of the blocks on the device. Choose one of the `dd` commands below,
depending on whether you want to pre-warm just the previously written blocks or the entire volume.
   - **Read-only:** To pre-warm only previously written blocks
This command pre-warms your existing data and any restored snapshots of volumes that have been previously fully pre-warmed.
This command maintains incremental snapshots; however, because this operation is read-only,
it does not pre-warm unused space that has never been written to on the original volume.

   The `if` (input file) parameter should be set to the drive you wish to warm. The `of` (output file)
   parameter should be set to the Linux null virtual device, /dev/null. The `bs` parameter sets
   the block size of the read operation; for optimal performance, this should be set to 1 MB.

```
[ec2-user ~]$ sudo dd if=/dev/xvdf of=/dev/null bs=1M
```
Read-then-write-back: To pre-warm an entire restored volume

This command reads each block from the device and then writes it back at the same location, which pre-warms the entire volume, including unused space that has never been pre-warmed. Because this command writes to every block on the device, the next snapshot on a volume that is pre-warmed this way will require a full snapshot.

The `if` (input file) parameter should be set to the drive you wish to warm. The `of` (output file) parameter should also be set to the drive you wish to warm. The `conv=notrunc` parameter instructs `dd` to overwrite each output file block instead of deleting it. The `bs` parameter sets the block size of the read operation; for optimal performance, this should be set to 1 MB.

```
[ec2-user ~]$ sudo dd if=/dev/xvdf of=/dev/xvdf conv=notrunc bs=1M
```

**Note**
This step may take several minutes up to several hours, depending on your EC2 instance bandwidth, the IOPS provisioned for the volume, and the size of the volume.

When the operation is finished, you will see a report of the read operation.

```
15360+0 records in
15360+0 records out
32212254720 bytes (32 GB) copied, 2480.02 s, 13.0 MB/s
```

Your volume is now ready for use. For more information, see Making an Amazon EBS Volume Available for Use (p. 532).

### Pre-Warming Amazon EBS Volumes on Windows

There are multiple ways to pre-warm EBS volumes on Windows. The most simple solution is to provide a full format of the volume. Use the following command to perform a full format of a new volume:

**Warning**
The following command will destroy any existing data on the volume.

```
C:\>format drive_letter: /p:1
```

You can also perform a full format by right-clicking on the drive in a Windows Explorer window and clicking **Format**. Because this operation destroys all data on the volume, it is only appropriate for new volumes.

For a more powerful pre-warming tool, which allows you to pre-warm volumes that have been restored from a snapshot or that contain existing data, you should consider **dd** for Windows.

### Install dd for Windows

The **dd** for the Windows program provides a similar experience to the **dd** program that is commonly available for Linux and Unix systems, and it allows you to pre-warm both new EBS volumes and volumes that have been restored from snapshots. At the time of this writing, the most recent beta version contains the `/dev/null` virtual device that is required to pre-warm volumes restored from snapshots. Full documentation for the program is available at [http://www.chrysocome.net/dd](http://www.chrysocome.net/dd).

1. Download the most recent binary version of **dd** for Windows from [http://www.chrysocome.net/dd](http://www.chrysocome.net/dd).
   You must use version 0.6 beta 3 or newer to pre-warm restored volumes.
2. (Optional) Create a folder for command line utilities that is easy to locate and remember, such as `C:\bin`. If you already have a designated folder for command line utilities, you can use that folder instead in the following step.
3. Unzip the binary package and copy the `dd.exe` file to your command line utilities folder (for example, `C:\bin`).

4. Add the command line utilities folder to your `Path` environment variable so you can execute the programs in that folder from anywhere.

   **Important**
   The following steps don’t update the environment variables in your current command prompt windows. The command prompt windows that you open after you complete these steps will contain the updates. This is why it’s necessary for you to open a new command prompt window to verify that your environment is set up properly.

   a. Click **Start**, right-click **Computer**, and then click **Properties**.
   b. Click **Advanced system settings**.
   c. Click **Environment Variables**.
   d. Under **System Variables**, click the variable called **Path** and then click **Edit**.
   e. In **Variable value**, append a semicolon and the location of your command line utility folder (`;C:\bin\`) to the end of the existing value.
   f. Click **OK** to close the **Edit System Variable** window.

---

**To Pre-Warm a Volume Using dd for Windows**

1. Use the `dd --list` command to list the available devices on your system.

   ```
   C:\>dd --list
   rawwrite dd for windows version 0.6beta3.
   Written by John Newbigin <jn@it.swin.edu.au>
   This program is covered by terms of the GPL Version 2.
   
   Win32 Available Volume Information
   \\.\Volume{6c195fc1-0511-11e3-9220-806e6f6e6963}\ link to \\?\Device\HarddiskVolume1
   fixed media
   Mounted on \\.\c:
   
   \\.\Volume{c608dec6-4280-11e3-89dd-123141015292}\ link to \\?\Device\HarddiskVolume2
   fixed media
   Mounted on \\.\z:
   ```

   You can use the **Volume** name, the **Device** name, or the drive letter (for example, `\\.\z:`) to identify the device you want to pre-warm in the following steps. If you want to completely wipe the drive, proceed to Step 2 (p. 571); if you want to preserve the data on a volume, proceed to Step 3 (p. 572).

2. (Optional: destructive pre-warm command) Execute the following command to write zeros (from the virtual device, `/dev/zero`) to the specified device that you identified in Step 1 (p. 571). The `bs=1M` flag uses a one megabyte block size (which speeds up the write process) and the `--progress` flag provides a status update as the write operation is conducted.

   **Warning**
   The following command will destroy any existing data on the volume. For volumes with existing data (such as volumes restored from snapshots), use the command in Step 3 (p. 572).

   ```
   C:\>dd if=/dev/zero of=\.\drive_letter: bs=1M --progress
   ```
3. (Optional: read-only pre-warm command) Execute the following command to read all blocks on the specified device (and send the output to the /dev/null virtual device). This command safely pre-warms your existing data and any restored snapshots of volumes that were fully pre-warmed.

```
C:\> dd if=\drive_letter: of=/dev/null bs=1M --progress
```

4. When the operation completes, you are ready to use your new volume. For more information, see Making an Amazon EBS Volume Available for Use (p. 532).

**RAID Configuration**

With Amazon EBS, you can use any of the standard RAID configurations that you can use with a traditional bare metal server, as long as that particular RAID configuration is supported by the operating system for your instance. This is because all RAID is accomplished at the software level. For greater I/O performance than you can achieve with a single volume, RAID 0 can stripe multiple volumes together; for on-instance redundancy, RAID 1 can mirror two volumes together.

The following table compares these two common striping options.

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Use</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAID 0</td>
<td>When I/O performance is more important than fault tolerance; for example, as in a heavily used database (where data replication is already set up separately).</td>
<td>I/O is distributed across the volumes in a stripe. If you add a volume, you get the straight addition of throughput.</td>
<td>Performance of the stripe is limited to the worst performing volume in the set. Loss of a single volume results in a complete data loss for the array.</td>
</tr>
<tr>
<td>RAID 1</td>
<td>When fault tolerance is more important than I/O performance; for example, as in a critical application.</td>
<td>Safer from the standpoint of data durability.</td>
<td>Does not provide a write performance improvement; requires more bandwidth than non-RAID configurations because the data is written to multiple volumes simultaneously.</td>
</tr>
</tbody>
</table>

**Important**

RAID 5 and RAID 6 are not recommended for Amazon EBS because the configurations do not provide optimum performance.

Creating a RAID 0 array allows you to achieve a higher level of performance for a file system than you can provision on a single Amazon EBS volume. A RAID 1 array offers a "mirror" of your data for extra redundancy. Before you perform this procedure, you need to decide how large your RAID array should be and how many IOPS you want to provision.

The resulting size of a RAID 0 array is the sum of the sizes of the volumes within it, and the bandwidth is the sum of the available bandwidth of the volumes within it. The resulting size and bandwidth of a RAID 1 array is equal to the size and bandwidth of the volumes in the array. For example, two 500 GiB Amazon EBS volumes with 4,000 provisioned IOPS each will create a 1 TiB RAID 0 array with an available bandwidth of 8,000 16K IOPS or a 500 GiB RAID 1 array with an available bandwidth of 4,000 16K IOPS.

Creating a RAID Array on Linux

To create a RAID array on Linux

1. Create the Amazon EBS volumes for your array. For more information, see Creating a New Amazon EBS Volume (p. 526).

   **Important**
   Create volumes with identical size and IOPS performance values for your array. Make sure you do not create an array that exceeds the available bandwidth of your EC2 instance. For more information, see Amazon EC2 Instance Configuration (p. 565).

2. Attach the Amazon EBS volumes to the instance that you want to host the array. For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529).

3. (Optional) Pre-warm your volumes. Amazon EBS volumes can experience between a 5 to 50 percent performance hit the first time you access a block on the volume. Pre-warming allows you to access each block on the volumes before you need to use them so that you can achieve full performance in a production workload. For more information, see Pre-Warming Amazon EBS Volumes (p. 568).

4. Use the `mdadm` command to create a logical RAID device from the newly attached Amazon EBS volumes. Substitute the number of volumes in your array for `number_of_volumes` and the device names for each volume in the array (such as `/dev/xvdf`) for `device_name`.

   **Note**
   You can list the devices on your instance with the `lsblk` command to find the device names.

   (RAID 0 only) To create a RAID 0 array, execute the following command (note the `--level=stripe` option to stripe the array):

   ```bash
   [ec2-user ~]$ sudo mdadm --create --verbose /dev/md0 --level=stripe --raid-devices=number_of_volumes device_name1 device_name2
   ```

   (RAID 1 only) To create a RAID 1 array, execute the following command (note the `--level=mirror` option to mirror the array):

   ```bash
   [ec2-user ~]$ sudo mdadm --create --verbose /dev/md0 --level=mirror --raid-devices=number_of_volumes device_name1 device_name2
   ```

5. Create a file system on your RAID device. For example, to create an `ext4` file system, execute the following command:

   ```bash
   [ec2-user ~]$ sudo mkfs.ext4 /dev/md0
   ```

   Depending on the requirements of your application or the limitations of your operating system, you may opt for a different file system type, such as ext3 or XFS.

6. Create a mount point for your RAID array.

   ```bash
   [ec2-user ~]$ sudo mkdir /mnt/md0
   ```

7. Finally, mount the RAID device on the mount point that you created:

   ```bash
   [ec2-user ~]$ sudo mount -t ext4 /dev/md0 /mnt/md0
   ```

   Your RAID device is now ready for use.
Creating a RAID Array on Windows

To create a RAID array on Windows

1. Create the Amazon EBS volumes for your array. For more information, see Creating a New Amazon EBS Volume (p. 526).

   Important
   Create volumes with identical size and IOPS performance values for your array. Make sure you do not create a array that exceeds the available bandwidth of your EC2 instance. For more information, see Amazon EC2 Instance Configuration (p. 565).

2. Attach the Amazon EBS volumes to the instance that you want to host the array. For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529).

3. Connect to your Windows instance. For more information, see Connecting to Windows Instances Using RDP (p. 317).

4. Open a command prompt and type the `diskpart` command.

   ```
   PS C:\Users\Administrator> diskpart
   Microsoft DiskPart version 6.1.7601
   Copyright (C) 1999-2008 Microsoft Corporation.
   On computer: WIN-BM6QPPL51CO
   ```

5. At the DiskPart prompt, list the available disks with the following command.

   ```
   DISKPART> list disk
   Disk ###  Status         Size     Free     Dyn  Gpt
   --------  -------------  -------  -------  ---  ---
   Disk 0    Online           30 GB      0 B
   Disk 1    Online            8 GB      0 B
   Disk 2    Online            8 GB      0 B
   Disk 3    Online            8 GB      0 B
   Disk 4    Online            8 GB      0 B
   Disk 5    Online          419 GB      0 B
   Disk 6    Online          419 GB      0 B
   ```

   Identify the disks you want to use in your array and take note of their disk numbers.

6. Each disk you want to use in your array must be a dynamic disk that does not contain any existing volumes. Use the following steps to convert basic disks to dynamic disks and to delete any existing volumes.

   a. Select a disk you want to use in your array with the following command, substituting `n` with your disk number.

      ```
      DISKPART> select disk n
      Disk n is now the selected disk.
      ```

   b. If the selected disk did not have an asterisk in the Dyn column in the previous `list disk` command output, you need to convert it to a dynamic disk.

      ```
      DISKPART> convert dynamic
      ```
c. Use the `detail disk` command to check for existing volumes on the selected disk.

```
DISKPART> detail disk

```

Note any volume numbers on the disk. In this example, the volume number is 2. If there are no volumes, you can skip the next step.

d. (Only required if volumes were identified in the previous step) Select and delete any existing volumes on the disk that you identified in the previous step.

**Warning**
This destroys any existing data on the volume.

i. Select the volume, substituting `n` with your volume number.

```
DISKPART> select volume n
Volume n is the selected volume.
```

ii. Delete the volume.

```
DISKPART> delete volume
DiskPart successfully deleted the volume.
```

iii. Repeat these substeps for each volume you need to delete on the selected disk.

e. Repeat Step 6 (p. 574) for each disk you want to use in your array.

7. Verify that the disks you want to use are now dynamic.

```
DISKPART> list disk
```
8. Create your raid array. On Windows, a RAID 0 volume is referred to as a striped volume and a RAID 1 volume is referred to as a mirrored volume.

(Striped volumes only) To create a striped volume array on disks 1 and 2, use the following command (note the `stripe` option to stripe the array):

```
DISKPART> create volume stripe disk=1,2
```

DiskPart successfully created the volume.

(Mirrored volumes only) To create a mirrored volume array on disks 3 and 4, use the following command (note the `mirror` option to mirror the array):

```
DISKPART> create volume mirror disk=3,4
```

DiskPart successfully created the volume.

```
DISKPART> list volume
```

<table>
<thead>

</tr>
</tbody>
</table>

Note that for this example the `Type` column lists a `Mirror` volume and a `Stripe` volume.

10. Select and format your volume so that you can begin using it.

a. Select the volume you want to format, substituting \( n \) with your volume number.

```
DISKPART> select volume n
```

Volume \( n \) is the selected volume.

b. Format the volume.

**Note**

To perform a full format, omit the `quick` option.
DISKPART> format quick recommended label="My new volume"
100 percent completed
DiskPart successfully formatted the volume.

c. Assign an available drive letter to your volume.

DISKPART> assign letter f
DiskPart successfully assigned the drive letter or mount point.

Your new volume is now ready to use.

**Benchmark Volumes**

This section demonstrates how you can test the performance of Provisioned IOPS volumes by simulating workloads similar to those of a database application. The process is as follows:

1. Launch an EBS-optimized instance
2. Create new Provisioned IOPS volumes
3. Attach the volumes to your EBS-optimized instance
4. Create a RAID array from the volumes, then format and mount it
5. Install a tool to benchmark I/O performance
6. Benchmark the I/O performance of your volumes
7. Delete your volumes and terminate your instance so that you don’t continue to incur charges

**Set Up Your Instance**

To get optimal performance from a Provisioned IOPS volume, we recommend that you use an EBS-optimized instance. EBS-optimized instances deliver dedicated throughput between Amazon EC2 and Amazon EBS, with options between 500 and 2,000 Mbps, depending on the instance type.

To create an EBS-optimized instance, select **Launch as an EBS-Optimized instance** when launching the instance using the EC2 console, or specify **--ebs-optimized** when using the command line. Be sure that you launch one of the instance types that supports this option. For the example tests in this topic, we recommend that you launch an **m1.xlarge** instance. For more information, see Amazon EBS-Optimized Instances (p. 114).

To create a Provisioned IOPS volume, select **Provisioned IOPS (io1)** when creating the volume using the EC2 console, or specify **--type io1 --iops iops** when using the command line. For information about attaching these volumes to your instance, see Attaching an Amazon EBS Volume to an Instance (p. 529).

For the example tests, we recommend that you create a RAID array with 6 volumes, which offers a high level of performance. Because you are charged by the gigabytes used and the number of provisioned IOPS, not the number of volumes, there is no additional cost for creating multiple, smaller volumes and using them to create a stripe set. If you’re using Oracle ORION to benchmark your volumes, it can simulate striping the same way that Oracle ASM does, so we recommend that you let ORION do the striping. If you are using a different benchmarking tool, you’ll need to stripe the volumes yourself.

For information about creating a striped volume on Windows, see Create a Striped Volume in Windows.
To create a six-volume stripe set on Linux, use a command like the following.

```
$ sudo mdadm --create /dev/md0 --level=0 --chunk=64 --raid-devices=6 /dev/sdf
   /dev/sdg /dev/sdh /dev/sdi /dev/sdj /dev/sdk
```

For this example, the file system we use is XFS. You should use the file system that meets your requirements. On Amazon Linux, use the following command to install the XFS file system.

```
$ sudo yum install -y xfsprogs
```

Then, use the following commands to create and mount the XFS file system.

```
$ sudo mkdir -p /media/p_iops_vol0 &&
   sudo mkfs.xfs /dev/md0 &&
   sudo mount -t xfs /dev/md0 /media/p_iops_vol0 &&
   sudo chown ec2-user:ec2-user /media/p_iops_vol0/
```

Finally, to get the most accurate results while running these tests, you must pre-warm the volume. For a completely new volume that was created from scratch, you should write to all blocks before using the volume. For a new volume created from a snapshot, you should read all the blocks that have data before using the volume. For example, on Linux you can read each block on the volume using the following command.

```
$ dd if=/dev/md0 of=/dev/null
```

On Windows, a full format of the volume pre-warms it. Use the `format <drive letter> /p:1` command to write zeros to the entire disk.

**Important**

Unless you pre-warm the volume, you might see between a 5 to 50 percent reduction in IOPS when you first access it.

### Install Benchmark Tools

The following are among the possible tools you can install and use to benchmark the performance of a Provisioned IOPS volume.

<table>

<td>For calibrating the I/O performance of storage systems to be used with Microsoft SQL Server. For information about how to improve the performance of your Microsoft SQL Server databases, see Optimizing Databases at the MSDN website.</td>
</tr>
</tbody>
</table>
Example Benchmarking Commands

These benchmarking tools support a wide variety of test parameters. You should use commands that approximate the workloads your volumes will support. These commands are intended as examples to help you get started.

Run the following commands on an EBS-optimized instance with attached Provisioned IOPS volumes that have been pre-warmed.

When you are finished testing your volumes, see these topics for help cleaning up: Deleting an Amazon EBS Volume (p. 547) and Terminate Your Instance (p. 325).

fio Commands

Run fio on the stripe set that you created.

By default, fio is installed in /usr/local/bin, which isn't in root's path. You should update your path, or use chmod to enable fio to be run as ec2-user.

The following command performs 16 KB random write operations.

```
fio --directory=/media/p_iops_vol0
    --name fio_test_file --direct=1 --rw=randwrite --bs=16k --size=1G
    --numjobs=16 --time_based --runtime=180 --group_reporting
```

The following command performs 16 KB random read operations.

```
fio --directory=/media/p_iops_vol0
    --name fio_test_file --direct=1 --rw=randread --bs=16k --size=1G
    --numjobs=16 --time_based --runtime=180 --group_reporting
```

For more information about interpreting the results, go to this Linux tutorial: Inspecting disk IO performance with fio.

Oracle ORION Commands

Run ORION on the Provisioned IOPS volumes, having it simulate Oracle ASM striping instead of providing it with a stripe set that uses Windows striping.

In the directory where you installed ORION, create a file, piops_test.lun, to specify the volumes for your stripe set. The following example file specifies six Provisioned IOPS volumes to be striped.

```
\.\D:
\.\E:
\.\F:
\.\G:
\.\H:
\.\I:
```

The following command performs 16 KB random I/O operations (80 percent reads and 20 percent writes), simulating 64 KB RAID-0 stripes.

```
orion -run advanced -testname piops_test -size_small 16 -size_large 16
    -type rand -simulate raid0 -stripe 64 -write 80 -matrix detailed -num_disks 6
```
After the command is finished, ORION generates output files with the results in the same directory. For more information about ORION, see its Documentation.

**SQLIO Commands**

Run SQLIO on the stripe set that you created.

Create a file, `param.txt`, to specify your striped set. The contents of this file should look something like this (here, `d:\` corresponds to the striped set, and the test uses 6 threads and a 10 GB file).

```
d:\bigtestfile.dat 6 0x0 10240
```

The following command performs 16 KB random data writes.

```
sqlio -kW -s600 -frandom -t8 -o8 -b16 -LS -BH -F param.txt
```

The following command performs 16 KB random data reads.

```
sqlio -kR -s600 -frandom -t8 -o8 -b16 -LS -BH -F param.txt
```

The results are displayed in the Command Prompt window. For more information about SQLIO, see the `readme.txt` file in your SQLIO installation directory.

**Amazon EBS API and Command Overview**

Amazon EC2 Instance Store

Each Amazon EC2 instance, unless it's a t1.micro instance, can access disk storage from disks that are physically attached to the host computer. This disk storage is referred to as *instance store*.

- Optimizing Disk Performance (p. 590)

**Instance Storage Concepts**

An instance store provides temporary block-level storage for use with an instance. The size of an instance store ranges from 150 GiB to up to 48 TiB, and varies by instance type. Larger instance types have larger instance stores. For more information, see Instance Stores Available on Instance Types (p. 583).

An instance store consists of one or more instance store volumes. Instance store volumes must be configured using block device mapping at launch time and mounted on the running instance before they can be used. By default, instances launched from an Amazon EBS-backed instance have no mounted instance store volumes. Instances launched from an instance store-backed AMI have a mounted instance store volume for the virtual machine's root device volume, and can have other mounted instances store volumes, depending on the instance type. For more information about instance store-backed AMIs and Amazon EBS-backed AMIs, see Storage for the Root Device (p. 50).

Instance store volumes are usable only from a single instance during its lifetime; they can't be detached and then attached to another instance. If you create an AMI from an instance, the data on its instance store volumes isn't preserved and isn't present on the instance store volumes for the instances that you launch from this AMI. While an instance store is dedicated to a particular instance, the disk subsystem is shared among instances on a host computer, as shown in the following figure.

![Instance Storage Diagram](image-url)
The data in an instance store persists only during the lifetime of its associated instance. If an instance reboots (intentionally or unintentionally), data in the instance store persists. However, data on instance store volumes is lost under the following circumstances:

- Failure of an underlying drive
- Stopping an Amazon EBS-backed instance
- Terminating an instance

Therefore, do not rely on instance store volumes for valuable, long-term data. Instead, keep your data safe by using a replication strategy across multiple instances, storing data in Amazon S3, or using Amazon EBS volumes. For more information, see Amazon Elastic Block Store (Amazon EBS) (p. 523).

When you launch an instance, whether it’s launched from an Amazon EBS-backed AMI or an instance store-backed AMI, you can attach instance store volumes to the instance using block device mapping. For more information, see Adding Instance Store Volumes to an AMI (p. 589).

### Instance Stores Available on Instance Types

Amazon EC2 instances are divided into different instance types, which determine the size of the instance store available on the instance by default. When you launch an instance, you can specify an instance type or use the default instance type, which is an m1.small instance.

The instance type also determines the type of hardware for your instance store volumes. Some instance types use solid state drives (SSD) to deliver very high random I/O performance. This is a good option when you need storage with very low latency, but you don’t need it to persist when the instance terminates, or you can take advantage of fault tolerant architectures. For more information see HI1 Instances (p. 107).

The following table shows the instance types along with the size and quantity of the instance store volumes available to each instance type; these instance store volumes are included as part of the instance’s hourly cost.

† The c1.medium and m1.small instance types also include a 900 MB instance store swap volume, which may not be automatically enabled at boot time. For more information, see Instance Store Swap Volumes (p. 584).

**Instance Store Swap Volumes**

Swap space in Linux can be used when a system requires more memory than it has been physically allocated. When swap space is enabled, Linux systems can swap infrequently used memory pages from physical memory to swap space (either a dedicated partition or a swap file in an existing file system) and free up that space for memory pages that require high speed access.

The c1.medium and m1.small instance types have a limited amount of physical memory to work with, and they are given a 900 MB swap volume at launch time to act as virtual memory for Linux AMIs. Although the Linux kernel sees this swap space as a partition on the root device, it is actually a separate instance store volume, regardless of your root device type.

Amazon Linux AMIs automatically enable and use this swap space, but your AMI may require some additional steps to recognize and use this swap space. To see if your instance is using swap space, you can use the `swapon -s` command.
The above instance has a 900 MB swap volume attached and enabled. If you don't see a swap volume listed with this command, you may need to enable swap space for the device. Check your available disks using the `lsblk` command.

```
[ec2-user@ip-12-34-56-78 ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk
```

Here, the swap volume `xvda3` is available to the instance, but it is not enabled (notice that the MOUNTPOINT field is empty). You can enable the swap volume with the `swapon` command.

**Note**

You need to prepend `/dev/` to the device name listed by `lsblk`. Your device may be named differently, such as `sda3`, `sde3`, or `xvde3`. Use the device name for your system in the command below.

```
[ec2-user@ip-12-34-56-78 ~]$ sudo swapon /dev/xvda3
```

Now the swap space should show up in `lsblk` and `swapon -s` output.

```
[ec2-user@ip-12-34-56-78 ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk [SWAP]
[ec2-user@ip-12-34-56-78 ~]$ swapon -s
Filename    Type      Size    Used    Priority
/dev/xvda3  partition 917500  0        -1
```

You will also need to edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user@ip-12-34-56-78 ~]$ sudo vim /etc/fstab
```

Append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvda3  none    swap    sw 0       0
```

## Instance Store Device Names

Within an instance store, instance store volumes are exposed as block devices. The virtual devices for instance store volumes are `ephemeral[0-3]`. Instance types that support one instance store volume have `ephemeral0`. Instance types that support two instance store volumes have `ephemeral0` and `ephemeral1`. Instance types that support four instance store volumes have `ephemeral0`, `ephemeral1`, `ephemeral2`, and `ephemeral3`.

Many instance store volumes are pre-formatted with the ext3 file system. SSD-based instance store volumes that support TRIM instruction are not pre-formatted with any file system. However, you can format volumes with the file system of your choice after you launch your instance. A Windows instance
uses a built-in tool, EC2Config Service, to reformat the instance store volumes available on an instance with the NTFS file system.

Every instance store-backed AMI and instance has a mapping of the instance store volumes attached to the instance. Each entry in the mapping consists of a device name and the volume that it’s mapped to. The instance store volumes are available to the instance, but you can’t access them until they are mounted. A Windows instance uses the EC2Config Service to mount the instance store volumes for an instance. On Linux, the instance type determines which instance store volumes are mounted for you and which are available for you to mount yourself. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different than the name that Amazon EC2 recommends.

The following table lists the devices names reserved for instance store volumes by instance type, and the default state of the storage device (formatted, mounted, available) on an instance store-backed instance. For example, an m1.small instance has ephemeral0 (ext3, 15 GiB) and swap (Linux swap, 896 MB).

An instance can have multiple instance store volumes mapped to a device. However, the number and size of these volumes must not exceed the instance store available for the instance type. For more information, see Instance Stores Available on Instance Types (p. 583).
Instance Store Usage Scenarios

Instance store volumes are ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content, or for data that is replicated across a fleet of instances, such as a load-balanced pool of web servers.

Making Instance Stores Available on Your Instances

Instances that use Amazon EBS for the root device do not, by default, have instance store available at boot time. Also, you can't attach instance store volumes after you've launched an instance. Therefore, if you want your Amazon EBS-backed instance to use instance store volumes, you must specify them using a block device mapping when you create your AMI or launch your instance. Examples of block device mapping entries are: /dev/sdb=ephemeral0 and /dev/sdc=ephemeral1. For more information about block device mapping, see Block Device Mapping (p. 592)

The following procedure describes how to launch an Amazon EBS-backed m1.large Windows instance with instance store volumes.

Launch Amazon EBS-backed Windows Instances with Instance Store Volumes

1. Locate an Amazon EBS-backed Windows AMI.
2. Add block device mapping entries for ephemeral0 and ephemeral1.
   For more information, see To add volumes to an instance (p. 599).
3. Connect to the instance.
5. Devices listed:
   • Local Disk C:/ 9.98GiB
   • Local Disk D:/ 419GiB
   • Local Disk E:/ 419GiB

6. Double-click Local Disk C:. You can see the list of installed applications. This is your root drive.
7. Double-click Local Disk D:/ and then double-click Local Disk E:. These drives are empty. They are the instance stores that come with your m1.large instance, and they are available for you to use with your applications.

The following procedure describes how to launch an Amazon EBS-backed m1.large Linux instance with instance store volumes.

Accessing Instance Stores on Amazon EBS-backed Linux Instances

1. Locate an Amazon EBS-backed Linux/Unix AMI.
2. Add block device mapping entries for ephemeral0 and ephemeral1.
   For more information, see To add volumes to an instance (p. 599).
3. Connect to the instance.
4. Verify the instance stores currently mounted on the disk.
5. Notice a 10GiB root partition mounted at / and a 420 GiB mounted on an /media/ephemeral0 volume. Your m1.large instance comes with 2 420 GiB instance store volumes; the second volume is available but must be mounted before it can be used.
6. To format and mount the other 420 GiB instance store volume:
a. Create a file system of your choice on the device /dev/sdc (requires root privileges).
b. Create a directory on which to mount the device.
c. Mount the device on the newly created directory.

7. Verify that the device has been mounted.
8. Optionally, list the files on the root device.

You can also map instance store volumes to block devices when you create an AMI. The instances launched from such an AMI have instance store volumes at boot time. For information about adding a block device mapping while creating an AMI, see Creating an Amazon EBS-Backed Linux AMI (p. 69).

The following procedure describes how to access the instance store volumes from within an Amazon EC2 instance store-backed m1.large Windows instance.

Depending on the instance type, some instance store volumes on Amazon EC2 instance store-backed Linux and Unix instances are not mounted when the instance is launched. For example, on an m1.large Linux and Unix instance, the device /dev/sdc, although formatted and available, must be mounted before it can be used.

The following procedure describes how to access the instance store from within Amazon EC2 instance store-backed m1.large Linux instance.

### Suppressing Instance Stores at Launch Time

You can prevent a particular instance storage volume from attaching to the instance. You can do this for both Amazon EC2 instance store-backed instances and Amazon EBS-backed instances. For example, specifying the mapping /dev/sdc=none when launching an instance prevents /dev/sdc from attaching to the instance. For more information about block device mapping, see Block Device Mapping (p. 592).

### Adding Instance Store Volumes to an AMI

Amazon EBS-backed AMIs don’t include an instance store by default. However, you might want instances launched from your Amazon EBS-backed AMIs to include instance store volumes.

After you add instance store volumes to an AMI, any instance you launch from the AMI includes these instance store volumes. You can confirm that the instance store devices are available from within the instance itself using instance metadata. For more information, see Viewing the Instance Block Device Mapping for Instance Store Volumes (p. 602).

For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

You can create an AMI that includes instance store volumes using the console or the command line.

#### To add instance store volumes to an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click **Instances**.
3. Select an instance and select **Create Image** from the **Actions** list.
4. In the **Create Image** dialog, add a meaningful name and description to your image.
5. For each instance store volume, Click **Add New Volume**, select an instance store volume from the **Type** list and a device name from **Device**.
6. Click **Create Image**.

#### To add instance store volumes to an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- create-image or register-image (AWS CLI)
• `ec2-create-image ec2-register` (Amazon EC2 CLI)

For more information, see Block Device Mapping (p. 592).

**Optimizing Disk Performance**

Because of the way that Amazon EC2 virtualizes disks, the first write to any location on a standard instance store volume performs more slowly than subsequent writes. For most applications, amortizing this cost over the lifetime of the instance is acceptable. However, if you require high disk performance, we recommend that you pre-warm your drives by writing once to every drive location before production use.

**Note**
The I2 high I/O instance type uses direct-attached solid state drives that provide maximum performance at launch time, without pre-warming.

If you require greater flexibility in latency or throughput, we recommend using Amazon EBS.

To pre-warm the instance storage volumes, use the following Linux/Unix `dd` commands, depending on which store you want to initialize (/dev/sdb, etc.).

**Note**
Make sure to unmount the drive before performing this command.
Initialization can take a long time (about 8 hours for an extra large instance).

To initialize the instance store volumes, use the following commands on the `m1.large, m1.xlarge, c1.xlarge, m2.xlarge, m2.2xlarge, and m2.4xlarge` instance types:

```
dd if=/dev/zero of=/dev/sdb bs=1M
dd if=/dev/zero of=/dev/sdc bs=1M
dd if=/dev/zero of=/dev/sdd bs=1M
dd if=/dev/zero of=/dev/sde bs=1M
```

For information about the instance storage that is available for each instance type, see Instance Stores Available on Instance Types (p. 583).

To perform initialization on all instance store volumes at the same time, use the following command:

```
dd if=/dev/zero bs=1M|tee /dev/sdb|tee /dev/sdc|tee /dev/sdd > /dev/sdd
```

Configuring drives for RAID initializes them by writing to every drive location. When configuring software-based RAID, make sure to change the minimum reconstruction speed:

```
echo $(30*1024) > /proc/sys/dev/raid/speed_limit_min
```

**Amazon Simple Storage Service (Amazon S3)**

Amazon S3 is a repository for Internet data. Amazon S3 provides access to reliable, fast, and inexpensive data storage infrastructure. It is designed to make web-scale computing easy by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. Amazon S3 stores data objects redundantly on multiple devices across multiple facilities and allows concurrent read or write access to these data objects by many separate clients or application threads. You can use the redundant data stored in Amazon S3 to recover quickly and reliably from instance or application failures.
Amazon EC2 uses Amazon S3 for storing Amazon Machine Images (AMIs). You use AMIs for launching EC2 instances. In case of instance failure, you can use the stored AMI to immediately launch another instance, thereby allowing for fast recovery and business continuity.

Amazon EC2 also uses Amazon S3 to store snapshots (backup copies) of the data volumes. You can use snapshots for recovering data quickly and reliably in case of application or system failures. You can also use snapshots as a baseline to create multiple new data volumes, expand the size of an existing data volume, or move data volumes across multiple Availability Zones, thereby making your data usage highly scalable. For more information about using data volumes and snapshots, see Amazon Elastic Block Store (p. 523).

Objects are the fundamental entities stored in Amazon S3. Every object stored in Amazon S3 is contained in a bucket. Buckets organize the Amazon S3 namespace at the highest level and identify the account responsible for that storage. Amazon S3 buckets are similar to Internet domain names. Objects stored in the buckets have a unique key value and are retrieved using a HTTP URL address. For example, if an object with a key value `/photos/mygarden.jpg` is stored in the `myawsbucket` bucket, then it is addressable using the URL `http://myawsbucket.s3.amazonaws.com/photos/mygarden.jpg`.

For more information about the features of Amazon S3, see the Amazon S3 product page.

**Amazon S3 and Amazon EC2**

Given the benefits of Amazon S3 for storage, you may decide to use this service to store files and data sets for use with EC2 instances. There are several ways to move data to and from Amazon S3 to your instances. In addition to the examples discussed below, there are a variety of tools that people have written that you can use to access your data in Amazon S3 from your computer or your instance. Some of the common ones are discussed in the AWS forums.

If you have permission, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

**GET or wget**

The `wget` utility is an HTTP and FTP client that allows you to download public objects from Amazon S3. It is installed by default in Amazon Linux and most other distributions, and is available for Windows. To download an Amazon S3 object, use the following command, substituting the URL of the object to download.

```bash
gwget http://s3.amazonaws.com/my_bucket/my_folder/my_file.ext
```

This method requires that the object you request is public; if the object is not public, you receive an **ERROR 403: Forbidden** message. If you receive this error, open the Amazon S3 console and change the permissions of the object to public. For more information, see the Amazon Simple Storage Service Developer Guide.

**AWS Command Line Interface**

The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With just one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts. The AWS CLI allows users to authenticate themselves and download restricted items from Amazon S3 and also to upload items. For more information, such as how to install and configure the tools, see the AWS Command Line Interface detail page.

The `aws s3 cp` command is similar to the Unix `cp` command (the syntax is: `aws s3 cp source destination`). You can copy files from Amazon S3 to your instance, you can copy files from your instance to Amazon S3, and you can even copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance.
Use the following command to copy an object from your instance back into Amazon S3.

```
aws s3 cp s3://my_bucket/my_folder/my_file.ext my_copied_file.ext
```

Use the following command to copy an object from one Amazon S3 location to another.

```
aws s3 cp s3://my_bucket/my_folder/my_file.ext s3://my_bucket/my_folder/my_file2.ext
```

The `aws s3 sync` command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. The command syntax is: `aws s3 sync source destination`. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance.

```
aws s3 sync s3://remote_S3_bucket local_directory
```

**AWS Tools for Windows PowerShell**

Windows instances have the benefit of a graphical browser that you can use to access the Amazon S3 console directly; however, for scripting purposes, Windows users can also use the AWS Tools for Windows PowerShell to move objects to and from Amazon S3.

Use the following command to copy an Amazon S3 object to your Windows instance.

```
Copy-S3Object -BucketName my_bucket -Key my_folder/my_file.ext -LocalFile my_copied_file_ext
```

**Amazon S3 API**

If you are a developer, you can use an API to access data in Amazon S3. For more information, see the Amazon Simple Storage Service Developer Guide. You can use this API and its examples to help develop your application and integrate it with other APIs and SDKs, such as the boto Python interface.

**Block Device Mapping**

Each Amazon EC2 instance that you launch has an associated root device volume, either an Amazon Elastic Block Store (EBS) volume or an instance store volume. You can use block device mapping to specify additional EBS volumes or instance store volumes to attach to an instance when it's launched. You can also attach additional EBS volumes to a running instance; see Attaching an Amazon EBS Volume to an Instance (p. 529). However, the only way to attach instance store volumes to an instance is to use block device mapping to attach them as the instance is launched.

For more information about root device volumes, see Changing the Root Device Volume to Persist (p. 16).

Block Device Mapping Concepts

A block device is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer. Amazon EC2 supports two types of block devices:

- Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
- Amazon EBS volumes (remote storage devices)

A block device mapping defines the block devices to be attached to an Amazon EC2 instance and the device name to use. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you launched the instance.

There are two types of virtualization available in Amazon EC2: Paravirtual and Hardware Virtual Machine (HVM). The virtualization type is determined by the AMI used to launch the instance; some instance types support both Paravirtual and HVM while others support only one or the other. Be sure to note the virtualization type used by your AMI when you are creating your block device mapping because the recommended and available device names that you can use are different based on the virtualization type of your instance.

Specifying a Block Device Mapping

Use a block device mapping to attach instance store volumes and EBS volumes to an Amazon EC2 instance.

When you create a block device mapping, you specify this information for each block device that you need to attach to the instance:

- The device name within Amazon EC2, as shown in this table. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 recommends.

**Important**

On some devices, the names that you specify in your block device mapping can conflict with the default block device names. To avoid this issue, do not use names of the form 
/dev/sda[2-15].

Hardware virtual machine (HVM) AMIs (such as the base Windows and Cluster Compute images) do not support the use of trailing numbers on device names (xvd[a-p][1-15]). You can view the virtualization type of your instance on the Virtualization field of the instance's details pane.

Depending on the block device driver of your instance's kernel, the device may be attached with a different name than what you specify. For example, if you specify a device name of /dev/sdh, your device may be renamed /dev/xvdh or /dev/hdh by the kernel; in some cases, even the trailing letter may also change (where /dev/sda could become /dev/xvde).

Amazon Linux AMIs create a symbolic link from the renamed device path to the name you specify, but other AMIs may behave differently.

- [Instance store volumes only] The virtual device: ephemeral[0-3].
- [EBS volumes only] The ID of the snapshot to use to create the block device (snap-xxxxxxxx). This value is optional as long as you specify a volume size.
- [EBS volumes only] The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
- [EBS volumes only] Whether to delete the volume on instance termination (true or false). The default value is true.
- [EBS volumes only] The volume type, which can be standard for standard EBS volumes or io1 for Provisioned IOPS volumes. The default value is standard.
- [EBS volumes only] The number of input/output operations per second (IOPS) that the volume supports. (Not used with standard volumes.)

**Example Block Device Mapping**

This figure shows an example block device mapping for an Amazon EBS–backed instance. It maps /dev/sdb to ephemeral0 and maps two EBS volumes, one to /dev/sdh and the other to /dev/sdj. It also shows the EBS volume that is the root device volume, /dev/sda1.
Note that this example block device mapping is used in the example commands and APIs in this topic. You can find example commands and APIs that create block device mappings here:

- Specifying a Block Device Mapping for an AMI (p. 596)
- Updating the Block Device Mapping when Launching an Instance (p. 599)

### How Devices Are Made Available in the Operating System

Device names like `/dev/sdh` and `xvdh` are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an Amazon EC2 instance. After a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

With a Linux instance, the device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots. The instance type determines which instance store volumes are formatted and mounted by default. You can mount additional instance store volumes at launch, as long as you don't exceed the number of instance store volumes available for your instance type. For more information, see Amazon EC2 Instance Store (p. 582). The block device driver for the instance determines which devices are used when the volumes are formatted and mounted. For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529).

With a Windows instance, the device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots, and then the Ec2Config service initializes and mounts the drives. The root device volume is mounted as C:\. The instance store volumes are mounted as D:\, E:\, and so on. When an EBS volume is mounted, it can be mounted using any available drive letter. However, you can configure how the Ec2Config Service assigns drive letters to EBS volumes; for more information, see Using EC2Config.
Viewing Block Device Mappings

You can view information about each block device in a block device mapping. For details, see:

- Viewing the EBS Volumes in an AMI Block Device Mapping (p. 598)
- Viewing the EBS Volumes in an Instance Block Device Mapping (p. 601)
- Viewing the Instance Block Device Mapping for Instance Store Volumes (p. 602)

AMI Block Device Mapping

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. An AMI that Amazon provides includes a root device only. To add more block devices to an AMI, you must create your own AMI.

Topics

- Specifying a Block Device Mapping for an AMI (p. 596)
- Viewing the EBS Volumes in an AMI Block Device Mapping (p. 598)

Specifying a Block Device Mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an instance store-backed AMI, you can add only instance store volumes using a block device mapping.

For M3 instances, you must specify instance store volumes in the block device mapping for the instance. When you launch an M3 instance, we ignore any instance store volumes specified in the block device mapping for the AMI.

To add volumes to an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click Instances.
3. Select an instance and select Create Image from the Actions list.
4. In the Create Image dialog box, click Add New Volume.
5. Select a volume type from the Type list and a device name from the Device list. For an EBS volume, you can optionally specify a snapshot, volume size, and EBS volume type.
6. Click Create Image.

To add volumes to an AMI using the AWS CLI

Use the create-image command to specify a block device mapping for an Amazon EBS-backed AMI. Use the register-image command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the following parameter:

```
--block-device-mappings [mapping, ...]
```
To add an instance store volume, use the following mapping:

```
{
  "DeviceName": "/dev/sdf",
  "VirtualName": "ephemeral0"
}
```

To add an empty 100 GiB EBS volume, use the following mapping:

```
{
  "DeviceName": "/dev/sdg",
  "Ebs": {
    "VolumeSize": 100
  }
}
```

To add an EBS volume based on a snapshot, use the following mapping:

```
{
  "DeviceName": "/dev/sdh",
  "Ebs": {
    "SnapshotId": "snap-xxxxxxxxx"
  }
}
```

To omit a mapping for a device, use the following mapping:

```
{
  "DeviceName": "/dev/sdj",
  "NoDevice": ""
}
```

To add volumes to an AMI using the Amazon EC2 CLI

Use the `ec2-create-image` command to specify a block device mapping for an Amazon EBS-backed AMI. Use the `ec2-register` command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the following parameter:

```
-b "devicename=blockdevice"
```

**devicename**

The device name within Amazon EC2

**blockdevice**

To omit a mapping for the device from the AMI, specify `none`.

To add an instance store volume, specify `ephemeral[0..3]`.

To add an EBS volume to an EBS-backed instance, specify

```
[snapshot-id]:[size]:[delete-on-termination]:[type]:[iops]
```

- To add an empty EBS volume, omit the snapshot ID and specify a volume size instead.
- To indicate whether the EBS volume should be deleted on termination, specify `true` or `false`; the default value is `true`.  

API Version 2014-02-01

597
To create a Provisioned IOPS volume, specify `io1`; the default type is `standard`. If the type is `io1`, you can also provision the number of IOPS the volume supports.

You can specify multiple block devices in a single command using multiple `-b` parameters. For example, the following parameters add an instance store volume as `/dev/sdb`, an EBS volume based on a snapshot as `/dev/sdh`, and an empty 100 GiB EBS volume as `/dev/sdj`.

```
-b "/dev/sdb=ephemeral0" -b "/dev/sdh=snap-d5eb27ab" -b "/dev/sdj=:100"
```

### Viewing the EBS Volumes in an AMI Block Device Mapping

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

**To view the EBS volumes for an AMI using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, click **AMIs**.
3. Select **EBS images** from the **Filter** drop-down list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the **Details** tab. At a minimum, the following information is available for the root device:
   - **Root Device Type** (ebs)
   - **Root Device Name** (for example, `/dev/sda1`)
   - **Block Devices** (for example, `/dev/sda1=snap-e1eb279f:8:true`)

   If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional EBS volumes as well. (Recall that this screen doesn’t display instance store volumes.)

**To view the EBS volumes for an AMI using the AWS CLI**

Use the `describe-images` command to enumerate the EBS volumes in the block device mapping for an AMI.

**To view the EBS volumes for an AMI using the Amazon EC2 CLI**

Use the `ec2-describe-images` command to enumerate the EBS volumes in the block device mapping for an AMI.

### Instance Block Device Mapping

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI. However, you can't modify the block device mapping entry for the root device volume.

**Topics**

Updating the Block Device Mapping when Launching an Instance

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn't make a permanent change to the block device mapping of the AMI from which it was launched.

To add volumes to an instance using the console

1. Open the Amazon EC2 console.
2. From the Amazon EC2 console dashboard, click Launch Instance.
3. On the Choose an Amazon Machine Image (AMI) page, choose the AMI to use and click Select.
4. Follow the wizard to complete the Choose an Instance Type and Configure Instance Details pages.
5. On the Add Storage page, you can modify the root volume, EBS volumes, and instance store volumes as follows:
   - To change the size of the root volume, locate the Root volume under the Type column, and change its Size field.
   - To suppress an EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the volume and click its Delete icon.
   - To add an EBS volume, click Add New Volume, select EBS from the Type list, and fill in the fields (Device, Snapshot, and so on).
   - To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume, and click its Delete icon.
   - To add an instance store volume, click Add New Volume, select Instance Store from the Type list, and select a device name from Device.
6. Complete the remaining wizard pages, and then click Launch.

To add volumes to an instance using the AWS CLI

Use the run-instances command to specify a block device mapping for an instance.

Specify the block device mapping using the following parameter:

```
--block-device-mappings [mapping, ...]
```

For example, suppose that an EBS-backed Linux AMI specifies the following block device mapping:

- /dev/sdb=ephemeral0
- /dev/sdh=snap-92d333fb
- /dev/sdj=:100

To prevent /dev/sdj from attaching to an instance launched from this AMI, use the following mapping:

```json
{
    "DeviceName": "/dev/sdj",
    "NoDevice": ""
}
```
To increase the size of /dev/sdh to 300 GiB, specify the following mapping. Notice that we don't need to specify the snapshot ID for /dev/sdh, because specifying the device name is enough to identify the volume.

```json
{
   "DeviceName": "/dev/sdh",
   "Ebs": {
      "VolumeSize": 300
   }
}
```

To attach an additional instance store volume, /dev/sdc, specify the following mapping. If the instance type doesn't support multiple instance store volumes, this mapping has no effect.

```json
{
   "DeviceName": "/dev/sdc",
   "VirtualName": "ephemeral1"
}
```

To add volumes to an instance using the Amazon EC2 CLI

Use the `ec2-run-instances` command to specify a block device mapping for an instance.

Specify the block device mapping using the following parameter:

```
-b "devicename=blockdevice"
```

`devicename`

The device name within Amazon EC2

`blockdevice`

To omit a mapping for the device from the AMI, specify `none`.

To add an instance store volume, specify `ephemeral[0..3]`.

To add an EBS volume to an EBS-backed instance, specify `[snapshot-id][size][delete-on-termination][type[iops]]`.
- To add an empty EBS volume, omit the snapshot ID and specify a volume size instead.
- To indicate whether the EBS volume is deleted on termination, specify `true` or `false`; the default value is `true`.
- To create a Provisioned IOPS volume, specify `io1`; the default type is `standard`. If the type is `io1`, you can also provision the number of IOPS the volume supports.

For example, suppose that an EBS-backed Linux AMI specifies the following block device mapping:

- /dev/sdb=ephemeral0
- /dev/sdh=snap-92d333fb
- /dev/sdj=:100

To prevent /dev/sdj from attaching to an instance launched from this AMI, use the following option:

```
-b "/dev/sdj=none"
```
To increase the size of /dev/sdh to 300 GiB, use the following option:

```
-b "/dev/sdh=:300"
```

Notice that we didn't need to specify the snapshot ID for /dev/sdh, because specifying the device name is enough to identify the volume.

To attach an additional instance store volume, /dev/sdc, use the following option. If the instance type doesn't support multiple instance store volumes, this option has no effect.

```
-b "/dev/sdc=ephemeral1"
```

### Viewing the EBS Volumes in an Instance Block Device Mapping

You can easily enumerate the EBS volumes mapped to an instance.

**Note**

For instances launched before the release of the 2009-10-31 API, AWS can't display the block device mapping. You must detach and reattach the volumes so that AWS can display the block device mapping.

#### To view the EBS volumes for an instance using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, click **Instances**.
3. Select **EBS root device** from the **Filter** list. This displays a list of Amazon EBS–backed instances.
4. Locate and click the desired instance and look at the details displayed in the **Description** tab. At a minimum, the following information is available for the root device:
   - **Root device type** (ebs)
   - **Root device** (for example, sda1)
   - **Block devices** (for example, sda1, sdh, and sdj)

If the instance was launched with additional EBS volumes using a block device mapping, the **Block devices** box displays those additional EBS volumes as well as the root device. (Recall that this dialog box doesn't display instance store volumes.)

```
Root device type: ebs
Root device: /dev/sda1
Block devices: /dev/sda1, /dev/sdh, /dev/sdj
```

5. To display additional information about a block device, click its entry next to **Block devices**. This displays the following information for the block device:
   - **EBS ID** (vol-xxxxxxxxx)
   - **Root device type** (ebs)
   - **Attachment time** (yyyy-mm-TThh:mm:ss.TZD)
   - **Block device status** (attaching, attached, detaching, detached)
   - **Delete on termination** (Yes, No)
To view the EBS volumes for an instance using the AWS CLI

Use the `describe-instances` command to enumerate the EBS volumes in the block device mapping for an instance.

To view the EBS volumes for an instance using the Amazon EC2 CLI

Use the `ec2-describe-instances` command to enumerate the EBS volumes in the block device mapping for an instance.

Viewing the Instance Block Device Mapping for Instance Store Volumes

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. You can use instance metadata to query the complete block device mapping. The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`.

First, connect to your running instance. If the instance is running Linux, the GET command is already available. If the instance is running Windows, install wget on the instance, and replace GET with wget in the examples below.

Use this query on a running instance to get its block device mapping.

```
```

The response includes the names of the block devices for the instance. For example, the output for a M1.small instance looks like this.

```
ami
ephemeral0
root
swap
```

The ami device is the root device as seen by the instance. The instance store volumes are named `ephemeral[0-3]`. The swap device is for the page file. If you've also mapped EBS volumes, they appear as `ebs1`, `ebs2`, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

Using Public Data Sets

- Public Data Set Concepts (p. 603)
- Finding Public Data Sets (p. 603)
- Creating a Public Data Set Volume from a Snapshot (p. 604)
- Attaching and Mounting the Public Data Set Volume (p. 605)

This section describes how to use public data sets with Amazon EC2.

Public Data Set Concepts

Amazon Web Services provides a repository of public data sets that can be seamlessly integrated into AWS cloud-based applications. Amazon stores the data sets at no charge to the community and, as with all AWS services, you pay only for the compute and storage you use for your own applications.

Previously, large data sets such as the mapping of the Human Genome and the US Census data required hours or days to locate, download, customize, and analyze. Now, anyone can access these data sets from an Amazon EC2 instance and start computing on the data within minutes. You can also leverage the entire AWS ecosystem and easily collaborate with other AWS users. For example, you can produce or use prebuilt server images with tools and applications to analyze the data sets. By hosting this important and useful data with cost-efficient services such as Amazon EC2, AWS hopes to provide researchers across a variety of disciplines and industries with tools to enable more innovation, more quickly.

For more information, go to the Public Data Sets on AWS Page.

Available Public Data Sets

Public data sets are currently available in the following categories:

- **Biology**—Includes Human Genome Project, GenBank, and other content.
- **Chemistry**—Includes multiple versions of PubChem and other content.
- **Economics**—Includes census data, labor statistics, transportation statistics, and other content.
- **Encyclopedic**—Includes Wikipedia content from multiple sources and other content.

Finding Public Data Sets

Before you can use a public data set, you must locate the data set and determine which format the data set is hosted in. The data sets are available in two possible formats: Amazon EBS snapshots or Amazon S3 buckets.

To find a public data set and determine its format

1. Go to the Public Data Sets Page to see a listing of all available public data sets. You can also enter a search phrase on this page to query the available public data set listings.
2. Click the name of a data set to see its detail page.
3. On the data set detail page, look for a snapshot ID listing to identify an Amazon EBS formatted data set or an Amazon S3 URL.
Data sets that are in Amazon EBS snapshot format are used to create new Amazon EBS volumes that you attach to an Amazon EC2 instance. For more information, see Creating a Public Data Set Volume from a Snapshot (p. 604).

For data sets that are in Amazon S3 format, you can use the AWS SDKs or the HTTP query API to access the information, or you can use the AWS CLI to copy or synchronize the data to and from your instance. For more information, see Amazon S3 and Amazon EC2 (p. 591).

You can also use Amazon Elastic MapReduce to analyze and work with public data sets. For more information, see What is Amazon EMR?.

## Creating a Public Data Set Volume from a Snapshot

To use a public data set that is in Amazon EBS snapshot format, you create a new volume, specifying the snapshot ID of the public data set. You can create your new volume using the AWS Management Console as follows. If you prefer, you can use the `ec2-create-volume` command instead.

### To create a public data set volume from a snapshot

1. Open the Amazon EC2 console.
2. From the navigation bar, select the region that your data set snapshot is located in.
   
   **Important**
   
   Snapshot IDs are constrained to a single region, and you cannot create a volume from a snapshot that is located in another region. In addition, you can only attach an Amazon EBS volume to an instance in the same Availability Zone. For more information, see Resource Locations (p. 606).
   
   If you need to create this volume in a different region, you can copy the snapshot to your required region and then restore it to a volume in that region. For more information, see Copying an Amazon EBS Snapshot (p. 561).
3. In the navigation pane, click **Volumes**.
4. Above the upper pane, click **Create Volume**.
5. In the **Create Volume** dialog box, in the **Type** list, select **Standard** or **Provisioned IOPS**. For more information, see Amazon EBS Volume Types (p. 525).
6. In the **Snapshot** field, start typing the ID or description of the snapshot for your data set. Select the snapshot from the list of suggested options.
   
   **Note**
   
   If the snapshot ID you are expecting to see does not appear, you may have a different region selected in the Amazon EC2 console. If the data set you identified in Finding Public Data Sets (p. 603) does not specify a region on its detail page, it is likely contained in the us-east-1 (N. Virginia) region.
7. In the **Size** field, enter the size of the volume (in GiB or TiB), or verify the that the default size of the snapshot is adequate.
   
   **Note**
   
   If you specify both a volume size and a snapshot ID, the size must be equal to or greater than the snapshot size. When you select a volume type and a snapshot ID, minimum and maximum sizes for the volume are shown next to the **Size** list.
8. For Provisioned IOPS volumes, in the **IOPS** field, enter the maximum number of input/output operations per second (IOPS) that the volume can support.
9. In the **Availability Zone** list, select the Availability Zone in which to launch the instance. For more information, see Regions and Availability Zones (p. 7).
**Important**

Amazon EBS volumes can only be attached to instances in the same Availability Zone. For more information, see Regions and Availability Zones (p. 7).

10. Click **Yes, Create**.

**Important**

If you created a larger volume than the default size for that snapshot (by specifying a size in Step 7 (p. 604)), you need to extend the file system on the volume to take advantage of the extra space. For more information, see Expanding the Storage Space of a Volume (p. 548).

---

### Attaching and Mounting the Public Data Set Volume

After you have created your new data set volume, you need to attach it to an Amazon EC2 instance to access the data (this instance must also be in the same Availability Zone as the new volume). For more information, see Attaching an Amazon EBS Volume to an Instance (p. 529).

After you have attached the volume to an instance, you need to mount the volume on the instance. For more information, see Making an Amazon EBS Volume Available for Use (p. 532).

### Listing and Filtering Your Resources

As part of using Amazon EC2, you might use different resources. These include images, instances, Amazon EBS volumes, and snapshots. You can get a list of some types of resource using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include only the resources that match certain criteria.

**Resource** | **Type** | **Description**
--- | --- | ---
User-Supplied Resource Names | Regional | Each resource name, such as a security group name or an SSH key pair name, is tied to its region and can be used only in the region where you created the resource. Although you can create resources with the same name in multiple regions, they aren't related to each other.

AMIs | Regional | An AMI is tied to the region where its files are located within Amazon S3. You can copy an AMI from one region to another. For more information, see Copying an AMI (p. 80).

Elastic IP Addresses | Regional | An Elastic IP address is tied to a region and can be associated only with an instance in the same region.

Security Groups | Regional | A security group is tied to a region and can be assigned only to instances in the same region. You can’t enable an instance to communicate with an instance outside its region using security group rules. Traffic from an instance in another region is seen as WAN bandwidth.

EBS Snapshots | Regional | An EBS snapshot is tied to its region and can only be used to create volumes in the same region. You can copy a snapshot from one region to another. For more information, see Copying an Amazon EBS Snapshot (p. 561).

EBS Volumes | Availability Zone | An Amazon EBS volume is tied to its Availability Zone and can be attached only to instances in the same Availability Zone.

Instances | Availability Zone | An instance is tied to the Availability Zones in which you launched it. However, note that its instance ID is tied to the region.

Listing Resources Using the Console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.

To list EC2 resources using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, click the option that corresponds to the resource, such as AMIs or Instances.
3. The page displays all the available resources.

Filtering Resources Using the Console

You can perform some basic filtering and sorting of the most common resource types using the Amazon EC2 console. Most pages in the console have at least one filtering list with a selection of options to help you find specific resources. For example, you can use the filter lists on the instances page to view only running instances.

You can also use the search field on each page to find resources with specific attributes or values. You can use regular expressions to search on partial or multiple strings. For example, to find all instances that are using the MySG security group, enter MySG in the search field. The results will include any values that contain MySG as a part of the string, such as MySG2 and MySG3. To limit your results to MySG only, enter \bMySG\b in the search field. To list all the instances whose type is either m1.small or m1.large, enter m1.small|m1.large in the search field.

For additional filtering capabilities, use the command line interface or the API actions.

To list volumes in the us-east-1b Availability Zone with a status of available

1. In the navigation pane, click Volumes.
2. Select **Detached volumes** from the filter list. (A detached volume is available to be attached to an instance in the same Availability Zone.)

3. Enter `us-east-1b` in the search field.

4. Any volumes that meet this criteria are displayed.

**To list public 64-bit Windows AMIs backed by Amazon EBS**

1. In the navigation pane, click **AMIs**.
2. In the **Filter** pane, select **Public images**, **EBS images** and **Windows** from the drop-down lists.
3. Enter `x86_64` in the search field.
4. Any AMIs that meet this criteria are displayed.

### Listing and Filtering Using the CLI and API

Each resource type has a corresponding CLI command or API request that you use to list resources of that type. For example, you can list Amazon Machine Images (AMI) using `ec2-describe-images` or `DescribeImages`. The response contains information for all your resources.

The resulting lists of resources can be long, so you might want to filter the results to include only the resources that match certain criteria. You can specify multiple filter values, and you can also specify multiple filters. For example, you can list all the instances whose type is either **m1.small** or **m1.large**, and that have an attached EBS volume that is set to delete when the instance terminates. The instance must match all your filters to be included in the results.

You can also use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches exactly one character. For example, you can use `*database*` as a filter value to get all EBS snapshots that include `database` in the description. If you were to specify `database` as the filter value, then only snapshots whose description equals `database` would be returned. Filter values are case sensitive. We support only exact string matching, or substring matching (with wildcards).

**Tip**

Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of `\*amazon\?\` searches for the literal string `*amazon?\`.

For a list of the available filters for a given EC2 resource, go to the relevant command:

- For Amazon EC2 CLI, see the relevant `ec2-describe` command in the *Amazon Elastic Compute Cloud Command Line Reference*.

  **Tip**

  If you’re using the Amazon EC2 command line tools on Windows, you might need to use quotation marks as shown in the examples.

- For AWS CLI, see the relevant `describe` command in the *AWS Command Line Interface Reference*.

- For Windows PowerShell, see the relevant `Get` command in the *AWS Tools for Windows PowerShell Reference*.

- For Query API, see the relevant `Describe` API action in the *Amazon Elastic Compute Cloud API Reference*. 
Tagging Your Amazon EC2 Resources

To help you manage your instances, images, and other Amazon Elastic Compute Cloud (Amazon EC2) resources, you can assign your own metadata to each resource in the form of tags. This topic describes tags and shows you how to create them.

Topics

- Tag Basics (p. 610)
- Tag Restrictions (p. 611)
- Tagging Your Resources for Billing (p. 612)
- Working with Tags in the Console (p. 612)
- API and CLI Overview (p. 617)

Tag Basics

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. Each tag consists of a key and a value, both of which you define. For example, you could define a set of tags for your account's Amazon EC2 instances that helps you track each instance's owner and stack level. We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add.

The following diagram illustrates how tagging works. In this example, you've assigned two tags to each of your instances, one called Owner and another called Stack. Each of the tags also has an associated value.

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources.

You can work with tags using the AWS Management Console, the Amazon EC2 command line interface (CLI), and the Amazon EC2 API.

You can assign tags only to resources that already exist. When you use the Amazon EC2 console, you can access a list of tags to add to an instance, which will be applied immediately after the instance is created. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set a tag's value to the empty string, but you can't set a tag's value to null.
If you’re using AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to create, edit, or delete tags. For more information about IAM, see Controlling Access to Amazon EC2 Resources (p. 448).

**Tag Restrictions**

The following basic restrictions apply to tags:

- Maximum number of tags per resource—10
- Maximum key length—127 Unicode characters
- Maximum value length—255 Unicode characters
- Tag keys and values are case sensitive.
- Do not use the `aws:` prefix in your tag names or values because it is reserved for AWS use. You can't edit or delete tag names or values with this prefix.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called `DeleteMe`, you must first get a list of those snapshots using `DescribeSnapshots` with a filter that specifies the tag. Then you use `DeleteSnapshots` with the resource identifiers of the snapshots (for example, `snap-1a2b3c4d`). You can't call `DeleteSnapshots` with a filter that specified the tag. For more information about using filters when listing your resources, see Listing and Filtering Your Resources (p. 607).

You can tag public or shared resources, but the tags you assign are available only to your AWS account and not to the other accounts sharing the resource.

You can't tag all resources, and some you can only tag using API actions or the command line. The following table lists all Amazon EC2 resources and the tagging restrictions that apply to them, if any. Resources with tagging restrictions of None can be tagged with API actions, the CLI, and the console.

Tagging Your Resources for Billing

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Cost Allocation and Tagging in About AWS Account Billing.

Working with Tags in the Console

Using the Amazon EC2 console, you can see which tags are in use across all of your Amazon EC2 resources in the same region. You can view tags by resource and by resource type, and you can also view how many items of each resource type are associated with a specified tag. You can also use the Amazon EC2 console to apply or remove tags from one or more resources at a time.

- Filtering a List of Resources by Tag (p. 616)

Displaying Tags

You can display tags in two different ways in the Amazon EC2 console. You can display the tags for an individual resource or for all resources.

To display tags for individual resources
When you select a resource-specific page in the Amazon EC2 console, it displays a list of those resources. For example, if you select Instances from the navigation pane, the console displays a list of Amazon EC2 instances. When you select a resource from one of these lists (e.g., an instance), if the resource supports tags, you can view and manage its tags. On most resource pages, you can view the tags in the Tags tab on the details pane. The following image shows the Tags tab for an instance with two tags:

- Name = DNS Server and Purpose = Network Management.

You can add a column to the resource list that displays all values for tags with the same key. This column enables you to sort and filter the resource list by the tag. There are two ways to add a new column to the resource list to display your tags:

- On the Tags tab, click Show Column for the tag.
- Click the Show/Hide Columns gear-shaped icon, and in the Show/Hide Columns dialog box, select the tag key under Your Tag Keys.

To display tags for all resources

You can display tags across all resources by selecting Tags from the navigation pane in the Amazon EC2 console. The following image shows the Tags pane, which lists all tags in use by resource type.

### Adding and Deleting Tags on an Individual Resource

You can manage tags for an individual resource directly from the resource's page. If you are managing an AMI's tags, the procedures are different from that of other resources. All procedures are explained below.

#### To add a tag to an individual resource

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. For more information, see Resource Locations (p. 606).
3. In the navigation pane, click a resource type (for example, **Instances**).
4. Select the resource from the resource list.
5. Select the **Tags** tab in the details pane.
6. Click the **Add/Edit Tags** button.
7. In the **Add/Edit Tags** dialog box, specify the key and value for each tag, and then click **Save**.

**To delete a tag from an individual resource**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. For more information, see Resource Locations (p. 606).
3. In the navigation pane, click a resource type (for example, **Instances**).
4. Select the resource from the resource list.
5. Select the **Tags** tab in the details pane.
6. Click **Add/Edit Tags**, click the **Delete** icon for the tag, and click **Save**.

**Adding and Deleting Tags to a Group of Resources**

**To add a tag to a group of resources**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. For more information, see Resource Locations (p. 606).
3. In the navigation pane, click **Tags**.

4. At the top of the content pane, click **Manage Tags**.

5. From the **Filter** drop-down list, select the type of resource (for example, instances) that you want to add tags to.

6. In the resources list, select the check box next to each resource that you want to add tags to.

7. In the **Key** and **Value** boxes under **Add Tag**, type the tag key and values you want, and then click **Add Tag**.

   **Note**
   If you add a new tag with the same tag key as an existing tag, the new tag overwrites the existing tag.

### To remove a tag from a group of resources

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. From the navigation bar, select the region that meets your needs. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. For more information, see Resource Locations (p. 606).

3. In the navigation pane, click **Tags**.

4. At the top of the content pane, click **Manage Tags**.

5. To view the tags in use, click the **Show/Hide Columns** gear-shaped icon, and in the **Show/Hide Columns** dialog box, select the tag keys you want to view, and then click **Close**.

6. From the **Filter** drop-down list, select the type of resource (for example, instances) that you want to remove tags from.

7. In the resource list, select the check box next to each resource that you want to remove tags from.

8. Under **Remove Tag**, click in the **Key** box to select a key, or type its name, and then click **Remove Tag**.
Adding a Tag When You Launch an Instance

To add a tag using the Launch Wizard

1. From the navigation bar, select the region for the instance. This choice is important because some Amazon EC2 resources can be shared between regions, while others can't. Select the region that meets your needs. For more information, see Resource Locations (p. 606).

2. Click the Launch Instance button on the EC2 dashboard.

3. The Choose an Amazon Machine Image (AMI) page displays a list of basic configurations called Amazon Machine Images (AMIs). Choose the AMI that you want to use and click its Select button. For more information about selecting an AMI, see Finding a Suitable AMI (p. 53).

4. On the Configure Instance Details page, configure the instance settings as necessary, and then click Next: Add Storage.

5. On the Add Storage page, you can specify additional storage volumes for your instance. Click Next: Tag Instance when done.

6. On the Tag Instance page, specify tags for the instance by providing key and value combinations. Click Create Tag to add more than one tag to your instance. Click Next: Configure Security Group when you are done.

7. On the Configure Security Group page, you can choose from an existing security group that you own, or let the wizard create a new security group for you. Click Review and Launch when you are done.

8. Review your settings. When you're satisfied with your selections, click Launch. Select an existing key pair or create a new one, select the acknowledgment check box, and then click Launch Instances.

Filtering a List of Resources by Tag

You can filter your list of resources based on one or more tag keys and tag values.

To filter a list of resources by tag

1. Display a column for the tag as follows:
   a. Select one of the resources.
b. Select the **Tags** tab in the details pane.

c. Locate the tag in the list and click **Show Column**.

2. Click the filter icon in the top right corner of the column for the tag to display the filter list.
3. Select the tag values, and then click **Apply Filter** to filter the results list.

---

## API and CLI Overview

Use the following API and CLI commands to add, update, list, and delete the tags for your resources. The documentation for each command provides examples. For more information about these command line interfaces, see *Accessing Amazon EC2* (p. 3).

<table>
<thead>
<tr>
<th>Description</th>

You can also filter a list of resources according to their tags. For example syntax, see *Filtering Resources Using the Console* (p. 608). For supported filters per resource, see the relevant command:

- For Amazon EC2 CLI, see the relevant `ec2-describe` command in the *Amazon Elastic Compute Cloud Command Line Reference*.
- For AWS CLI, see the relevant `describe` command in the *AWS Command Line Interface Reference*. 
Amazon EC2 Usage Reports

The usage reports provided by Amazon EC2 enable you to analyze the usage of your instances in depth. The data in the usage reports is updated multiple times each day. You can filter the reports by AWS account, region, Availability Zone, operating system, instance type, purchasing option, tenancy, and tags.

To get usage and cost data for an account, you must have its account credentials and enable detailed billing reports with resources and tags for the account. If you're using consolidated billing and are logged into the payer account, you can view data for the payer account and all its linked accounts. If you're using consolidated billing and are logged into one of the linked accounts, you can only view data for that linked account. For information about consolidated billing, see Pay Bills for Multiple Accounts with Consolidated Billing.

Available Reports

You can generate the following reports:

• Instance usage report (p. 620). This report covers your usage of on-demand instances, Spot Instances, and Reserved Instances.
• Reserved Instances utilization report (p. 624). This report covers the usage of your capacity reservation.

Getting Set Up for Usage Reports

Before you begin, enable detailed billing reports with resources and tags as shown in the following procedure. After you complete this procedure, we'll start collecting usage data for your instances. If you've already enabled detailed billing reports, you can access the usage data that we've been collecting since you enabled them.

Important

To complete these procedures, you must log in using your AWS account credentials. You can't complete these procedures if you log in using IAM user credentials.

To enable detailed billing reports

1. Select an existing Amazon S3 bucket to receive your usage data. Be sure to manage access to this bucket as it contains your billing data. (We don't require that you keep these files; in fact, you can delete them immediately if you don't need them.) If you don't have a bucket, create one as follows:
   a. Open the Amazon S3 console.
   b. Click Create Bucket.
c. In the Create a Bucket dialog box, enter a name for your bucket (for example, username-ec2-usage-data), select a region, and then click Create. For more information about the requirements for bucket names, see Creating a Bucket in the Amazon Simple Storage Service Console User Guide.

2. Open the Billing console at https://console.aws.amazon.com/billing/home?#.
3. Click Preferences in the navigation pane.
4. Select Receive Billing Reports.
5. Specify the name of your Amazon S3 bucket in Save to S3 Bucket, and then click Verify.
6. Grant AWS permission to publish usage data to your Amazon S3 bucket.
   a. Under Receive Billing Reports, click sample policy. Copy the sample policy. Notice that the sample policy uses the bucket name you specified.
   b. Open the Amazon S3 console in another browser tab. Select your bucket, click Properties, and then expand Permissions. In the Permissions section, click Add bucket policy. Paste the sample policy into the text area and click Save. In the Permissions section, click Save.
   c. Return to the browser tab with the sample policy and click Done.

7. Under Report, select Detailed billing report with resources and tags.
8. Click Save preferences.
   Note
   It can take up to a day before you can see your data in the reports.

You can categorize your instances using tags. After you tag your instances, you must enable reporting on these tags.

To enable usage reporting by tag

1. Tag your instances. For best results, ensure that you add each tag you plan to use for reporting to each of your instances. For more information about how to tag an instance, see Tagging Your Amazon EC2 Resources (p. 610).
2. Open the Billing console at https://console.aws.amazon.com/billing/home?#.
3. Click Preferences in the navigation pane.
5. The page displays the list of tags that you've created. Select the tags that you'd like to use to filter or group your instance usage data, and then click Save. We automatically exclude any tags that you don't select from your instance usage report.
   Note
   We apply these changes only to the data for the current month. It can take up to a day for these changes to take effect.

Granting IAM Users Access to the Amazon EC2 Usage Reports

By default, IAM users can’t access the Amazon EC2 usage reports. You must create an IAM policy that grants IAM users permission to access these reports.

The following policy allows users to view both Amazon EC2 usage reports.
The following policy allows users to view the instance usage report.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2-reports:ViewInstanceUsageReport",
    "Resource": "*"
  }]
}
```

The following policy allows users to view the Reserved Instances utilization report.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2-reports:ViewReservedInstanceUtilizationReport",
    "Resource": "*"
  }]
}
```

For more information, see Permissions and Policies in the Using IAM guide.

## Instance Usage Report

You can use the instance usage report to view your instance usage and cost trends. You can see your usage data in either instance hours or cost. You can choose to see hourly, daily and monthly aggregates of your usage data. You can filter or group the report by region, Availability Zone, instance type, AWS account, platform, tenancy, purchase option, or tag. After you configure a report, you can bookmark it so that it's easy to get back to later.

Here's an example of some of the questions that you can answer by creating an instance usage report:

- How much am I spending on instances of each instance type?
- How many instance hours are being used by a particular department?
- How is my instance usage distributed across Availability Zones?
- How is my instance usage distributed across AWS accounts?

**Topics**

- Report Formats (p. 621)
Report Formats

We display the usage data that you request as both a graph and a table.

For example, the following graph displays cost by instance type. The key for the graph indicates which color represents which instance type. To get detailed information about a segment of a bar, hover over it.

The corresponding table displays one column for each instance type. Notice that we include a color band in the column head that is the same color as the instance type in the graph.
Viewing Your Instance Usage

The following procedures demonstrate how to generate usage reports using some of the capabilities we provide.

Before you begin, you must get set up. For more information, see Getting Set Up for Usage Reports (p. 618).

To filter and group your instance usage by instance type

1. Open the Amazon EC2 console.
2. In the navigation pane, click Reports and then click EC2 Instance Usage Report.
3. Select an option for Unit. To view the time that your instances have been running, in hours, select Instance Hours. To view the cost of your instance usage, select Cost.
4. Select options for Granularity and Time range.
   - To view the data summarized for each hour in the time range, select Hourly granularity. You can select a time range of up to 2 days when viewing hourly data.
   - To view the data summarized for each day in the time range, select Daily granularity. You can select a time range of up to 2 months when viewing daily data.
   - To view the data summarized for each month in the time range, select Monthly granularity.
5. In the Filter list, select Instance Type. In the Group by list, select Instance Type.
6. In the filter area, select one or more instance types and then click Update Report. The filters you specify appear under Applied Filters.

Notice that you can return to the Amazon EC2 console by clicking either Reports or EC2 Management Console at the top of the page.
To group your instance usage based on tags

1. Open the Instance Usage Reports page.
2. Select an option for Unit. To view the time that your instances have been running, in hours, select Instance Hours. To view the cost of your instance usage, select Cost.
3. Select options for Granularity and Time range.
   - To view the data summarized for each hour in the time range, select Hourly granularity. You can select a time range of up to 2 days when viewing hourly data.
   - To view the data summarized for each day in the time range, select Daily granularity. You can select a time range of up to 2 months when viewing daily data.
   - To view the data summarized for each month in the time range, select Monthly granularity.
4. In the Group by list, select Tag.
5. Click the Key Name box, select a name from the list, and then click Update Report. If there are no items in this list, you must enable usage reporting by tag. For more information, see To enable usage reporting by tag (p. 619).

Bookmarking a Customized Report

You might want to generate a customized report again. Do this by bookmarking the report.

To bookmark a custom report

1. Select the options and filters for your report. Each selection you make adds a parameter to the console URL. For example, granularity=Hourly and Filters=filter_list.
2. Using your browser, add the console URL as a bookmark.
3. To generate the same report in the future, use the bookmark that you created.

Exporting Your Usage Data

You might want to include your report graph or table in other reports. Do this by exporting the data.

To export usage data

1. Select the options and filters for your report.
2. To export the usage data from the table as a .csv file, click Download and select CSV Only.
3. To export the graphical usage data as a .png file, click Download and select Graph Only.
Reserved Instance Utilization Reports

The Reserved Instance utilization report describes the utilization over time of each group (or bucket) of Amazon EC2 Reserved Instances that you own. Each bucket has a unique combination of region, Availability Zone, instance type, tenancy, offering type, and platform. You can specify the time range that the report covers, from a single day to weeks, months, a year, or three years. The available data depends on when you enable detailed billing reports for the account (see Getting Set Up for Usage Reports (p. 618)). The Reserved Instance utilization report compares the Reserved Instance prices paid for instance usage in the bucket with On-Demand prices and shows your savings for the time range covered by the report.

Note
The Reserved Instance buckets aggregate Reserved Instances across Amazon VPC and non-Amazon VPC (EC2 Classic) network platform types in the same way that your bill is calculated. Additionally, Reserved Instances in a bucket may have different upfront and hourly prices.

Here are examples of some of the questions that you can answer using the Reserved Instance utilization report:

- How well am I utilizing my Reserved Instances?
- Are my Reserved Instances helping me save money?

For information about Reserved Instances, see Reserved Instances (p. 198).

Before you begin, you must get set up. For more information, see Getting Set Up for Usage Reports (p. 618).

Getting to Know the Report

The Reserved Instance utilization report displays your requested utilization data in graph and table formats.
The report aggregates Reserved Instance usage data for a given period by bucket. In the report, each row in the table represents a bucket and provides the following metrics:

- **Count**—The highest number of Reserved Instances owned at the same time during the period of the report.
- **Usage Cost**—The total Reserved Instance usage fees applied to instance usage covered by the Reserved Instance bucket.
- **Total Cost**—The usage cost plus the amortized upfront fee for the usage period associated with the Reserved Instance bucket.

  **Note**
  If the bucket contains a Reserved Instance that you sold in the Reserved Instances Marketplace and that Reserved Instance was active at any point during the period of the report, the total cost of the bucket might be inflated and your savings might be underestimated.

- **Savings**—The difference between what your usage for the period would have cost at On-Demand prices and what it actually cost using Reserved Instances (Total Cost).
- **Average Utilization**—The average hourly utilization rate for the Reserved Instance bucket over the period.
- **Maximum Utilization**—The highest utilization rate of any hour during the period covered by the report.

For each row—or Reserved Instance bucket—in the table, the graph represents data based on your selected **Show** metric over the selected **Time range** for the report. Each point in the graph represents a metric at a point in time. For information about report options, see Options Reference (p. 628).

A color band at the edge of each selected row in the table corresponds to a report line in the graph. You can show a row in the graph by selecting the checkbox at the beginning of the row.
By default, the Reserved Instance utilization report returns data over the last 14 days for all Reserved Instance buckets. The graph shows the average utilization for the first five buckets in the table. You can customize the report graph to show different utilization (average utilization, maximum utilization) or cost (total cost, usage cost) data over a period ranging from a day to weeks, months, or years.

For example, the following report table shows Reserved Instance utilization for a two-month period. In this case, the period is December 1 through January 31. The report has been filtered to only return data about Reserved Instance buckets in eu-west-1a, eu-west-1b, and eu-west-1c.

The graph shows the daily Reserved Instance average utilization for the selected buckets.

**Customizing the Report**

You can customize the Reserved Instance utilization report with **Time range** and **Filter** options.
**Time range** provides a list of common relative time ranges, ranging from **Today** to **Last 3 Years**. Select the time range that works best for your needs, and then click **Update Report** to apply the change. To apply a time range that is not on the list, select **Custom** and enter the start date and end date for which you want to run the report.

**Filter** lets you scope your Reserved Instance utilization report by one or more of the following Reserved Instance qualities: region, instance type, account, platform, tenancy, and offering type. For example, you can filter by region or by specific Availability Zones in a region, or both. To filter by region, select **Regions**, then select the regions and Availability Zones you want to include in the report, and click **Update Report**.

The report will return all results if no filter is applied.

For information about report options, see **Options Reference** (p. 628).
Bookmarking a Customized Report

You might want to generate a customized report again. Do this by bookmarking the report.

To bookmark a custom report

1. Select the options and filters for your report. Each selection you make adds a parameter to the console URL. For example, granularity=Hourly and Filters=filter_list.
2. Using your browser, add the console URL as a bookmark.
3. To generate the same report in the future, use the bookmark that you created.

Exporting Your Usage Data

You might want to include your report graph or table in other reports. Do this by exporting the data.

To export usage data

1. Select the options and filters for your report.
2. To export the usage data from the table as a .csv file, click Download and select CSV Only.
3. To export the graphical usage data as a .png file, click Download and select Graph Only.

Options Reference

Use the Show options to specify the metric to be displayed by the report graph.

- Average Utilization
  Shows the average of the utilization rates for each hour over the selected time range, where the utilization rate of a bucket for an hour is the number of instance hours used for that hour divided by the total number of Reserved Instances owned in that hour.

- Maximum Utilization
  Shows the highest of the utilization rates of any hour over the selected time range, where the utilization rate of a bucket for an hour is the number of instance hours used for that hour divided by the total number of Reserved Instances owned in that hour.

- Usage Cost
  Shows the total cost based on hourly fees for a selected bucket of Reserved Instances. For heavy utilization Reserved Instance buckets, usage cost is calculated by multiplying the number of hours in the time frame by the hourly rates associated with the Reserved Instances in the bucket. For medium and light utilization Reserved instances, usage cost is calculated by multiplying the number of instance hours used for the selected time frame by the hourly rates for the respective Reserved Instances in the bucket.

- Total Cost
  Shows the usage cost plus the amortized portion of the upfront cost of the Reserved Instances in the bucket over the period for which the report is generated.

Use Time range to specify the period on which the report will be based.

Note
  All times are specified in UTC time.

- Today
Shows data for usage that takes place during any of the hours for the current calendar day. Can be used with hourly, daily, or monthly granularities.

- Last 2 Days

Shows data for usage that took place during the current and previous one calendar day. Can be used with hourly, daily, or monthly granularities.

- Last 7 Days

Shows data for usage that took place during the current and previous six calendar days. Can be used with daily or monthly granularities.

- Last 14 Days

Shows data for usage that took place during the current and previous 13 calendar days. Can be used with daily or monthly granularities.

- This Month

Shows data for usage that took place during the current calendar month. Can be used with daily or monthly granularities.

- Last 2 Months

Shows data for usage that took place during the current and previous calendar months. Can be used with daily or monthly granularities.

- Last 6 Months

Shows data for usage that took place during the current and previous five calendar months. Can be used with monthly granularities.

- Last 12 Months

Shows data for usage that took place during the current and previous 11 calendar months. Can be used with monthly granularity.

- This Year

Shows data for usage that took place during the current calendar year. Can be used with monthly granularity.

- Last 3 Years

Shows data for usage that took place during the current and previous two calendar years. Can be used with monthly granularity.

- Custom

Shows data for the time range for the entered Start and End dates specified in the following format: mm/dd/yyyy. Can be used with hourly, daily, or monthly granularities, but you can only specify a maximum time range of two days for hourly data, two months for daily data, and three years for monthly data.

For additional help with Windows instances, see Troubleshooting Windows Instances in the Amazon Elastic Compute Cloud Microsoft Windows Guide.

You can also search for answers and post questions on the Amazon EC2 forum.

What To Do If An Instance Immediately Terminates

After you launch an instance, we recommend that you check its status to confirm that it goes from the pending status to the running status, the not terminated status.

The following are a few reasons why an Amazon EBS-backed instance might immediately terminate:

- You've reached your volume limit. For information about the volume limit, and to submit a request to increase your volume limit, see Request to Increase the Amazon EBS Volume Limit.
- The AMI is missing a required part.
- The snapshot is corrupt.
Getting the Reason for Instance Termination

You can use the Amazon EC2 console, CLI, or API to get information about the reason that the instance terminated.

To get the reason that an instance terminated using the console
1. Open the Amazon EC2 console.
2. In the navigation pane, click **Instances** to display the instance details.
3. Select your instance.
4. In the **Description** tab, locate the reason next to the label **State transition reason**. If the instance is still running, there's typically no reason listed. If you've explicitly stopped or terminated the instance, the reason is **User initiated shutdown**.

To get the reason that an instance terminated using the command line
1. Use the `ec2-describe-instances` command in verbose mode as follows:

   ```
PROMPT> ec2-describe-instances instance_id -v
   ```

2. In the XML response that's displayed, locate the **stateReason** element. It looks similar to the following example.

   ```xml
   <stateReason>
   <code>Client.UserInitiatedShutdown</code>
   <message>Client.UserInitiatedShutdown: User initiated shutdown</message>
   </stateReason>
   ```

   This example response shows the reason code that you'll see after you stop or terminate a running instance. If the instance terminated immediately, you'll see **code** and **message** elements that describe the reason that the instance terminated (for example, **VolumeLimitExceeded**).

Troubleshooting Connecting to Your Instance

The following are possible problems you may have and error messages you may see while trying to connect to your instance.

**Topics**
- Error connecting to your instance: Connection timed out (p. 632)
- Error: User key not recognized by server (p. 633)
- Error: Host key not found, Permission denied (publickey), or Authentication failed, permission denied (p. 634)
- Error: Unprotected Private Key File (p. 635)
- Error: Server refused our key or No supported authentication methods available (p. 635)
- Error using MindTerm on Safari Browser (p. 635)

For additional help with Windows instances, see **Troubleshooting Windows Instances** in the *Amazon Elastic Compute Cloud Microsoft Windows Guide*.

You can also search for answers and post questions on the **Amazon EC2 forum**.
Error connecting to your instance: Connection timed out

If you try to connect to your instance and get an error message `Network error: Connection timed out` or `Error connecting to [instance], reason: -> Connection timed out: connect`, try the following:

- Check your security group rules. You need a security group rule that allows inbound traffic to the proper port(s) from your public IP address. When you use SSH to connect to your Linux instance, this is usually port 22. When you use RDP to connect to your Windows instance, this is usually port 3389. For more information, see Authorizing Network Access to Your Instances (p. 483).
- [EC2-VPC] Check the route table for the subnet. You need a route that sends all traffic destined outside the VPC (`0.0.0.0/0`) to the Internet gateway for the VPC.
- Check the CPU load on your instance; the server may be overloaded. AWS automatically provides data such as Amazon CloudWatch metrics and instance status, which you can use to see how much CPU load is on your instance and, if necessary, adjust how your loads are handled. For more information, see Monitoring Your Instances with CloudWatch (p. 364).
  - If your load is variable, you can automatically scale your instances up or down using Auto Scaling and Elastic Load Balancing.
  - If your load is steadily growing, you can move to a larger instance type. For more information, see Resizing Your Instance (p. 118).
- Verify that you are using the private key file that corresponds to the key pair that was selected when the instance was launched. For more information, see Amazon EC2 Key Pairs (p. 433).
- Verify that you are connecting with the appropriate user name for your AMI.
  - For an Amazon Linux AMI, the user name is `ec2-user`.
  - For a RHEL5 AMI, the user name is often `root` but might be `ec2-user`.
  - For an Ubuntu AMI, the user name is `ubuntu`.
  - Otherwise, check with your AMI provider.

If you are using MindTerm to connect, enter the user name in the **User name** box in the **Connect To Your Instance** window.

If you are using PuTTY to connect, enter the user name in the **Host name** box in the **PuTTY Configuration** window.
Error: User key not recognized by server

If you use SSH to connect to your instance

- Use `ssh -vvv` to get triple verbose debugging information while connecting:

```bash
#ssh -vvv -i [your key name].pem ec2-user@[public DNS address of your instance].compute-1.amazonaws.com
```

The following sample output demonstrates what you might see if you were trying to connect to your instance with a key that was not recognized by the server:

```

If you use SSH (MindTerm) to connect to your instance

- If Java is not enabled, the server does not recognize the user key. To enable Java, see How do I enable Java in my web browser? in the Java documentation.

If you use PuTTY to connect to your instance

- Verify that your private key (.pem) file has been converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connecting to Linux/Unix Instances from Windows Using PuTTY (p. 312).

  Note
  In PuTTYgen, load your private key file and select Save Private Key rather than Generate.

- Verify that you are connecting with the appropriate user name for your AMI. Enter the user name in the Host name box in the PuTTY Configuration window.
  - For an Amazon Linux AMI, the user name is ec2-user.
  - For a RHEL5 AMI, the user name is often root but might be ec2-user.
  - For an Ubuntu AMI, the user name is ubuntu.
  - Otherwise, check with your AMI provider.

- Verify that you have an inbound security group rule to allow inbound traffic to the appropriate port. For more information, see Authorizing Network Access to Your Instances (p. 483).

Error: Host key not found, Permission denied (publickey), or Authentication failed, permission denied

If you connect to your instance using SSH and get any of the following errors, Host key not found in [directory], Permission denied (publickey), or Authentication failed, permission denied, verify that you are connecting with the appropriate user name for your AMI and that you have specified the proper private key (.pem) file for your instance. For MindTerm clients, enter the user name in the User name box in the Connect To Your Instance window.

The appropriate user names are as follows:

- For an Amazon Linux AMI, the user name is ec2-user.
• For a RHEL5 AMI, the user name is often root but might be ec2-user.
• For an Ubuntu AMI, the user name is ubuntu.
• Otherwise, check with your AMI provider.

**Error: Unprotected Private Key File**

Your private key file must be protected from read and write operations from any other users. If your private key can be read or written to by anyone but you, then SSH ignores your key and you see the following warning message below.

```
@         WARNING: UNPROTECTED PRIVATE KEY FILE!          @
Permissions 0777 for ".ssh/my_private_key.pem" are too open.
It is required that your private key files are NOT accessible by others.
This private key will be ignored.
bad permissions: ignore key: .ssh/my_private_key.pem
Permission denied (publickey).
```

If you see a similar message when you try to log in to your instance, examine the first line of the error message to verify that you are using the correct public key for your instance. The above example uses the private key `ssh/my_private_key.pem` with file permissions of 0777, which allow anyone to read or write to this file. This permission level is very insecure, and so SSH ignores this key. To fix the error, execute the following command, substituting the path for your private key file.

```
$ chmod 0400 .ssh/my_private_key.pem
```

**Error: Server refused our key or No supported authentication methods available**

If you use PuTTY to connect to your instance and get either of the following errors, Error: Server refused our key or Error: No supported authentication methods available, verify that you are connecting with the appropriate user name for your AMI. Enter the user name in the User name box in the PuTTY Configuration window.

The appropriate user names are as follows:

• For an Amazon Linux AMI, the user name is ec2-user.
• For a RHEL5 AMI, the user name is often root but might be ec2-user.
• For an Ubuntu AMI, the user name is ubuntu.
• Otherwise, check with your AMI provider.

**Error using MindTerm on Safari Browser**

If you use MindTerm to connect to your instance, and are using the Safari 6.1 or 7 web browser, you may get the following error:
Error connecting to your_instance_ip, reason:
   -> Key exchange failed: Host authentication failed

You need to update the browser’s security settings to allow the AWS Management Console to run the Java plugin in unsafe mode.

**To enable the Java plugin to run in unsafe mode**

1. In Safari, keep the Amazon EC2 console open, and select Safari, then Preferences, then Security.
2. Click Manage Website Settings.
3. Select the Java plugin on the left, then locate the AWS Management Console URL in the Currently Open Websites list. Select Run in Unsafe Mode from its associated list.
4. When prompted, click Trust in the warning dialog. Click Done to return the browser.

### Troubleshooting Stopping Your Instance

If you have stopped your Amazon EBS-backed instance and it appears “stuck” in the stopping state, there may be an issue with the underlying host computer.

First, try stopping the instance again. If you are using the stop-instances (AWS CLI) or ec2-stop-instances (Amazon EC2 CLI) command, be sure to use the --force option.

If you can’t force the instance to stop, you can create an AMI from the instance and launch a replacement instance.

**To create a replacement instance**

1. Open the Amazon EC2 console.
2. In the navigation pane, click Instances and select the instance.
3. Click Actions and then click Create Image.
4. In the Create Image dialog box, fill in the following fields and then click Create Image:
   a. Specify a name and description for the AMI.
   b. Select No reboot.
5. Launch an instance from the AMI and verify that the instance is working.
6. Select the stuck instance, click Actions, and then click Terminate. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:

**To create a replacement instance (if the previous procedure fails)**

1. Select the instance, open the Description tab, and view the Block devices list. Select each volume and write down its volume ID. Be sure to note which volume is the root volume.
2. In the navigation pane, click Volumes. Select each volume for the instance, click Actions, and then click Create Snapshot.
3. In the navigation pane, click Snapshots. Select the snapshot that you just created, and then select Create Volume from the Actions list.
4. Launch an instance of the same type as the stuck instance (Amazon Linux, Windows, and so on). Note the volume ID and device name of its root volume.

5. In the navigation pane, click **Instances**, select the instance that you just launched, and then click **Stop**.

6. In the navigation pane, click **Volumes**, select the root volume of the stopped instance, click **Actions**, and then click **Detach Volume**.

7. Select the root volume that you created from the stuck instance, click **Attach Volume**, and attach it to the new instance as its root volume (using the device name that you wrote down). Attach any additional non-root volumes to the instance.

8. In the navigation pane, click **Instances** and select the replacement instance. Click **Actions** and then click **Start**. Verify that the instance is working.

9. Select the stuck instance, click **Actions**, and then click **Terminate**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

If you're unable to complete these procedures, you can post a request for help to the Amazon EC2 forum. To help expedite a resolution, include the instance ID and describe the steps that you've already taken.

## Troubleshooting Terminating (Shutting Down) Your Instance

You are not billed for any instance hours while an instance is not in the **running** state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to **shutting-down**.

### Delayed Instance Termination

If your instance remains in the **shutting-down** state longer than a few minutes, it might be delayed due to shutdown scripts being run by the instance.

Another possible cause is a problem with the underlying host computer. If your instance remains in the **shutting-down** state for several hours, Amazon EC2 treats it as a stuck instance and forcibly terminates it.

If it appears that your instance is stuck terminating and it has been longer than several hours, post a request for help to the Amazon EC2 forum. To help expedite a resolution, include the instance ID and describe the steps that you've already taken.

### Automatically Launch or Terminate Instances

If you terminate all your instances, you may see that we launch a new instance for you. If you launch an instance, you may see that we terminate one of your instances. Generally, these behaviors mean that you’ve used Auto Scaling or AWS Elastic Beanstalk to scale your computing resources automatically based on criteria that you’ve defined.

For more information, see the [Auto Scaling Developer Guide](https://docs.aws.amazon.com/autoscaling/ec2 User Guide) or the [AWS Elastic Beanstalk Developer Guide](https://docs.aws.amazon.com/elasticbeanstalk).
Troubleshooting Instances with Failed Status Checks

Topics

• Initial Steps You Can Take (p. 638)
• Troubleshooting Instance Status Checks for Linux-Based Instances (p. 638)

Initial Steps You Can Take

If your instance fails a status check, first determine whether your applications are exhibiting any problems. If you verify that the instance is not running your applications as expected, follow these steps:

To investigate impaired instances using the AWS Management Console

1. Open the Amazon EC2 console.
2. In the navigation pane, click Instances, and then select your instance.
3. Click the Status Checks tab in the details pane to see the individual results for all System Status Checks and Instance Status Checks.

If a system status check has failed, you can try one of the following options:

• For an instance using an Amazon EBS-backed AMI, stop and re-start the instance.
• For an instance using an instance-store backed AMI, terminate the instance and launch a replacement.
• Wait for Amazon EC2 to resolve the issue.
• Post your issue to the Amazon EC2 forum.

If an instance status check fails, follow these steps:

1. Right-click your instance, and then click Reboot. It may take a few minutes for your system to restart.
2. Verify that the problem still exists; in some cases, rebooting may resolve the problem.
3. Wait until the instance shows a running state.
4. Right-click the instance and then click Get System Log. You can use this information to help identify the problem. Be sure that you rebooted recently to clear unnecessary information from the log.
5. Review the log that appears on the screen.
6. Use the list of known system log error statements below to troubleshoot your issue.
7. If your experience differs from the our check results, or if you are having an issue with your instance that our checks did not detect, click Submit feedback at the bottom of the Status Checks tab to help us improve our detection tests.
8. If your issue is not resolved, you can post your issue to the Amazon EC2 forum.

Troubleshooting Instance Status Checks for Linux-Based Instances

For Linux-based instances that have failed an instance status check, such as the instance reachability check, verify that you followed the steps discussed earlier to retrieve the system log. The following list
contains some common system log errors and suggested actions you can take to resolve the issue for each error.

**Memory Errors**

**Tip**<br>The sixth field in the fstab defines availability requirements of the mount – a nonzero value implies that an fsck will be done on that volume and must succeed. Using this field can be problematic in Amazon EC2 because a failure typically results in an interactive console prompt which is not currently available in Amazon EC2. Use care with this feature and read the Linux man page for fstab.

Troubleshooting Instance Capacity

The following errors are related to instance capacity.

**Error: InsufficientInstanceCapacity**

If you get an InsufficientInstanceCapacity error when you try to launch an instance, AWS does not currently have enough available capacity to service your request. If you are requesting a large number of instances, there might not be enough server capacity to host them. You can try again later or specify a smaller number of instances.

**Error: InstanceLimitExceeded**

If you get an InstanceLimitExceeded error when you try to launch an instance, you have reached your concurrent running instance limit. For new AWS accounts, the default limit is 20. If you need additional running instances, complete the form at Request to Increase Amazon EC2 Instance Limit.
Getting Console Output and Rebooting Instances

Console output is a valuable tool for problem diagnosis. It is especially useful for troubleshooting kernel problems and service configuration issues that could cause an instance to terminate or become unreachable before its SSH daemon can be started.

Similarly, the ability to reboot instances that are otherwise unreachable is valuable for both troubleshooting and general instance management.

Amazon EC2 instances do not have a physical monitor through which you can view their console output. They also lack physical controls that allow you to power up, reboot, or shut them down. To allow these actions, we support these tasks through the Amazon EC2 API and the command line interface tools (CLI).

Instance Reboot

Just as you can reset a computer by pressing the reset button, you can reset Amazon EC2 instances using the Amazon EC2 console, CLI, or API. For more information, see Reboot Your Instance (p. 322).

Caution
For Windows instances, this operation performs a hard reboot that might result in data corruption.

Instance Console Output

For Linux/Unix instances, the instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. This output is buffered because the instance produces it and then posts it to a store where the instance's owner can retrieve it.

For Windows instances, the instance console output displays the last three system event log errors.

The posted output is not continuously updated; only when it is likely to be of the most value. This includes shortly after instance boot, after reboot, and when the instance terminates.

Note
Only the most recent 64 KB of posted output is stored, which is available for at least 1 hour after the last posting.

Only the instance owner can access the console output. You can retrieve the console output for your instances using the console or the command line.

To get console output using the console

1. Open the Amazon EC2 console.
2. Select the instance.
3. Click Actions and then click Get System Log.

To get console output using the command line

You can use one of the following commands. For more information about these command line interfaces, see Accessing Amazon EC2 (p. 3).

- get-console-output (AWS CLI)
- ec2-get-console-output (Amazon EC2 CLI)
Instance Recovery When its Host Computer Fails

If there is an unrecoverable issue with the hardware of an underlying host computer, AWS may schedule an instance stop event. You'll be notified of such an event ahead of time by email.

If you have an Amazon EBS-backed instance running on a host computer that fails, you can do the following to recover:

1. Back up any important data on your instance store volumes to Amazon EBS or Amazon S3.
2. Stop the instance.
3. Start the instance.
4. Restore any important data.
5. [EC2-Classic] If the instance had an associated Elastic IP address, you must reassociate it with the instance.

For more information, see Stop and Start Your Instance (p. 319).

If you have an instance store-backed instance running on a host computer that fails, you can do the following to recover:

1. Create an AMI from the instance.
2. Upload the image to Amazon S3.
3. Back up important data to Amazon EBS or Amazon S3.
4. Terminate the instance.
5. Launch a new instance from the AMI.
6. Restore any important data to the new instance.
7. [EC2-Classic] If the original instance had an associated Elastic IP address, you must associate it with the new instance.

For more information, see Creating an Instance Store-Backed Linux AMI (p. 72).
Making API Requests

We provide the Query API for Amazon EC2, as well as software development kits (SDK) for Amazon Web Services (AWS) that enable you to access Amazon EC2 from your preferred programming language.

To monitor the calls made to the Amazon EC2 API for your account, including calls made by the AWS Management Console, command line tools, and other services, use AWS CloudTrail. For more information, see the AWS CloudTrail User Guide.

Topics

• Required Knowledge (p. 664)
• Available APIs for Amazon EC2 (p. 664)
• Query Requests (p. 665)
• Troubleshooting API Request Errors (p. 668)
• Ensuring Idempotency (p. 670)
• SOAP Requests (p. 672)

Required Knowledge

If you plan to access Amazon EC2 through an API, you should be familiar with the following:

• XML
• Web services
• HTTP requests
• One or more programming languages, such as Java, PHP, Perl, Python, Ruby, C#, or C++.

Available APIs for Amazon EC2

The Amazon EC2 Query API provides HTTP or HTTPS requests that use the HTTP verb GET or POST and a Query parameter named Action. For more information about these API actions, see the Amazon Elastic Compute Cloud API Reference.

AWS provides libraries, sample code, tutorials, and other resources for software developers who prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS. These libraries provide basic functions that automatically take care of tasks such as cryptographically
signing your requests, retrying requests, and handling error responses, so that it is easier for you to get started.

For more information about downloading the AWS SDKs, see AWS SDKs and Tools. For more information about the language-specific APIs for Amazon EC2, see the following documentation.

**Query Requests**

Query requests are HTTP or HTTPS requests that use the HTTP verb GET or POST and a Query parameter named `Action`. For a list of Amazon EC2 API actions, see Actions.

**Topics**
Structure of a GET Request

The Amazon EC2 documentation presents the GET requests as URLs, which can be used directly in a browser.

**Tip**
Because the GET requests are URLs, you must URL encode the parameter values. In the Amazon EC2 documentation, we leave the example GET requests unencoded to make them easier to read.

The request consists of the following:

- **Endpoint**: The URL that serves as the entry point for the web service.
- **Action**: The action that you want to perform (for example, use `RunInstance` to run an instance).
- **Parameters**: Any parameters for the action; each parameter is separated by an ampersand (&). You must also include authorization parameters that AWS uses to ensure the validity and authenticity of the request. Amazon EC2 supports Signature Version 2. For more information, see Query API Authentication (p. 667).

The following is an example request that launches instances:

```
https://ec2.amazonaws.com/?Action=RunInstances&ImageId=ami-2bb65342&MaxCount=3&MinCount=1&Placement.AvailabilityZone=us-east-1b&Monitoring.Enabled=true&AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Version=2014-02-01&Expires=2010-10-10T12:00:00Z&Signature=1BP67vCvG1DMBQ1dofZxg8E8SUEXAMPLE&SignatureVersion=2&SignatureMethod=HmacSHA256
```

To make these example requests even easier to read, the Amazon EC2 documentation presents them in the following format:

```
https://ec2.amazonaws.com/?Action=RunInstances&ImageId=ami-2bb65342&MaxCount=3&MinCount=1&Placement.AvailabilityZone=us-east-1b&Monitoring.Enabled=true&AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Version=2014-02-01&Expires=2010-10-10T12:00:00Z&Signature=1BP67vCvG1DMBQ1dofZxg8E8SUEXAMPLE&SignatureVersion=2&SignatureMethod=HmacSHA256
```

The first line specifies the endpoint of the request. After the endpoint is a question mark (?), which separates the endpoint from the parameters.

The **Action** parameter indicates the action to perform. For a complete list of actions, see **Actions** in the Amazon Elastic Compute Cloud API Reference.
The remaining lines specify additional parameters for the request.

**Important**
Before you specify your access key ID for the `AWSAccessKeyId` parameter, review and follow the guidance in Best Practices for Managing AWS Access Keys.

## Endpoints

An endpoint is a URL that serves as an entry point for a web service. You can select a regional endpoint for Amazon EC2 when you make your requests to reduce latency. For more information about regions, see Region and Availability Zone Concepts (p. 7). For information about the endpoints for Amazon EC2, see Regions and Endpoints in the Amazon Web Services General Reference.

If you specify the general endpoint, `ec2.amazonaws.com`, we use the endpoint for `us-east-1`. To use a different region, specify its associated endpoint. For example, if you specify `ec2.us-west-2.amazonaws.com` as the endpoint, we direct your request to the `us-west-2` endpoint.

## Query Parameters

Each Query request must include required common parameters to handle authentication and selection of an action. For more information, see Common Query Parameters in the Amazon Elastic Compute Cloud API Reference.

Some operations take lists of parameters. These lists are specified using the `param.n` notation, where `n` is an integer starting from 1.

The following example adds multiple devices to a block device mapping using a list of `BlockDeviceMapping` parameters.

```
http://ec2.amazonaws.com/?Action=RunInstances
&ImageId.1=ami-72aa081b
...
&BlockDeviceMapping.1.DeviceName=/dev/sdj
&BlockDeviceMapping.1.Ebs.NoDevice=true
&BlockDeviceMapping.2.DeviceName=/dev/sdh
&BlockDeviceMapping.2.Ebs.VolumeSize=300
&BlockDeviceMapping.3.DeviceName=/dev/sdc
&BlockDeviceMapping.3.VirtualName=ephemeral1
&AUTHPARAMS
```

## Query API Authentication

You can send Query requests over either the HTTP or HTTPS protocol.

Regardless of which protocol you use, you must include a signature in every Query request. Amazon EC2 supports Signature Version 2. For more information, see Signature Version 2 Signing Process in the Amazon Web Services General Reference.

In the example Query requests we present in the Amazon EC2 documentation, we omit the parameters related to authentication to make it easier for you to focus on the parameters for the action. We replace them with the following literal string to remind you that you must include these parameters in your request: 

```
&AUTHPARAMS
```
Query Response Structures

In response to a Query request, the service returns an XML data structure that conforms to an XML schema defined as part of the WSDL file for Amazon EC2. The structure of an XML response is specific to the associated request. In general, the response data types are named according to the operation performed and whether the data type is a container (can have children). Examples of containers include groupSet for security groups and keySet for key pairs (see the example that follows). Item elements are children of containers, and their contents vary according to the container's role.

Every response includes a request ID in a requestId element. The value is a unique string that AWS assigns. If you ever have issues with a particular request, AWS will ask for the request ID to help troubleshoot the issue. The following shows an example response.

```
<DescribeKeyPairsResponse xmlns="http://ec2.amazonaws.com/doc/2014-02-01/">
  <requestId>7a62c49f-347e-4fc4-9331-6e8eEXAMPLE</requestId>
  <keySet>
    <item>
      <keyName>gsg-keypair</keyName>
      <keyFingerprint>
        00:00:00:00:00:00:00:00:00:00:00:00:00:00:00:00:00:00:00:00
      </keyFingerprint>
    </item>
  </keySet>
</DescribeKeyPairsResponse>
```

Troubleshooting API Request Errors

In the Amazon EC2 Query API, errors codes are indicated as being either client or server. Client errors usually occur because there is a problem with the structure, content, or validity of the request. Server errors usually indicate a server-side issue.

For more information about API error codes, see Error Codes in the Amazon Elastic Compute Cloud API Reference.

Topics
- Query API Request Rate (p. 668)
- Eventual Consistency (p. 669)
- Unauthorized Operation (p. 670)

Query API Request Rate

We throttle Amazon EC2 API requests for each AWS account to help the performance of the service. We ensure that all calls to the Amazon EC2 API (whether they originate from an application, calls to the Amazon EC2 command line interface, or the Amazon EC2 console) don't exceed the maximum allowed API request rate. Note that API requests made by IAM users are attributed to the underlying AWS account.

The Amazon EC2 API actions are divided into the following categories:
- Describe actions, such as DescribeInstances and DescribeVolumes. These requests simply retrieve cached data, so they have the highest request limit.
- Modify actions, such as RunInstances and CreateVolumes. These requests create or modify resources, so they have a lower request limit than describe calls.
• The `CreateKeyPair`, `GetConsoleOutput`, `AuthorizeSecurityGroupIngress`, and `RevokeSecurityGroupIngress` actions. These requests take the most time and resource to complete, so they have the lowest request limit.

If an API request exceeds the API request rate for its category, the request returns the `RequestLimitExceeded` error code. To prevent this error, ensure that your application doesn't retry API requests at a high rate. You can do this by using care when polling and by using exponential back-off retries.

**Polling**

Your application might need to call an API repeatedly to check for an update in status. Before you start polling, give the request time to potentially complete. When you begin polling, use an appropriate sleep interval between successive requests. For best results, use an increasing sleep interval.

**Retries or batch processing**

Your application might need to retry an API request after it fails, or to process multiple resources (for example, all your volumes). To lower the rate of API requests, use an appropriate sleep interval between successive requests. For best results, use an increasing or variable sleep interval.

**Calculating the sleep interval**

When you have to poll or retry an API request, we recommend using an exponential backoff algorithm to calculate the sleep interval between API calls. The idea behind exponential backoff is to use progressively longer waits between retries for consecutive error responses. For more information, and implementation examples of this algorithm, see Error Retries and Exponential Backoff in AWS.

**Eventual Consistency**

The Amazon EC2 API follows an eventual consistency model, due to the distributed nature of the system supporting the API. This means that the result of an API command you run that affects your Amazon EC2 resources might not be immediately visible to all subsequent commands you run. You should keep this in mind when you carry out an API command that immediately follows a previous API command.

Eventual consistency can affect the way you manage your resources. For example, if you run a command to create a resource, it will eventually be visible to other commands. This means that if you run a command to modify or describe the resource that you just created, its ID might not have propagated throughout the system, and you will get an error responding that the resource does not exist.

To manage eventual consistency, you can do the following:

• Confirm the state of the resource before you run a command to modify it. Run the appropriate `Describe` command using an exponential backoff algorithm to ensure that you allow enough time for the previous command to propagate through the system. To do this, run the `Describe` command repeatedly, starting with a couple of seconds of wait time, and increasing gradually up to five minutes of wait time.

• Add wait time between subsequent commands, even if a `Describe` command returns an accurate response. Apply an exponential backoff algorithm starting with a couple of seconds of wait time, and increase gradually up to about five minutes of wait time.

**Eventual Consistency Error Examples**

The following are examples of error codes you may encounter as a result of eventual consistency.

• `InvalidInstanceID.NotFound`
If you successfully run the `RunInstances` command, and then immediately run another command using the instance ID that was provided in the response of `RunInstances`, it may return an `InvalidInstanceID.NotFound` error. This does not mean the instance does not exist.

Some specific commands that may be affected are:

- **DescribeInstances**: To confirm the actual state of the instance, run this command using an exponential back-off algorithm.
- **TerminateInstances**: To confirm the state of the instance, first run the `DescribeInstances` command using an exponential back-off algorithm.

**Important**

If you get an `InvalidInstanceID.NotFound` error after running `TerminateInstances`, this does not mean that the instance is or will be terminated. Your instance could still be running. This is why it is important to first confirm the instance's state using `DescribeInstances`.

- **InvalidGroup.NotFound**

If you successfully run the `CreateSecurityGroup` command, and then immediately run another command using the instance ID that was provided in the response of `CreateSecurityGroup`, it may return an `InvalidGroup.NotFound` error. To confirm the state of the security group, run the `DescribeSecurityGroups` command using an exponential back-off algorithm.

### Unauthorized Operation

By default, AWS Identity and Access Management (IAM) users don't have permission to create or modify Amazon EC2 resources, or perform tasks using the Amazon EC2 API, unless they've been explicitly granted permission through IAM policies. If an IAM user attempts to perform an action for which permission has not been granted, the request returns the following error: `Client.UnauthorizedOperation`.

This error may occur when a policy is unintentionally restrictive. For example, to allow an IAM user to launch instances into a specific subnet, you need to grant permissions for the following resources by specifying their ARNs in your IAM policy: instances, volumes, AMIs, the specific subnet, network interfaces, key pairs, and security groups. If you omit the permission for volumes, for example, the user is only able to launch an instance from an instance store-backed AMI, as they do not have permission to create the root EBS volume for an EBS-backed instance.

For more information about creating IAM policies for Amazon EC2, see IAM Policies for Amazon EC2 (p. 450).

Currently, not all API actions support resource-level permissions; we'll add support for more in 2014. For more information about which ARNs you can use with which Amazon EC2 API actions, see Granting IAM Users Required Permissions for Amazon EC2 Resources in the Amazon Elastic Compute Cloud API Reference.

### Ensuring Idempotency

An idempotent operation completes no more than one time.

When you launch an instance, the request typically returns before the operation has completed. You determine whether the operation was successful by monitoring the state of the instance (it goes from pending to running). If the operation times out or there are connection issues, you might need to retry the request. However, if the original request and a retry both successful, you'll end up with more instances than you intended to launch.
If you launch an instance using the `ec2-run-instances` command or the `RunInstances` API action, you can optionally provide a client token to ensure that the request is idempotent. If you repeat a request, the same response is returned for each repeated request. The only information that might vary in the response is the state of the instance.

The client token is a unique, case-sensitive string of up to 64 ASCII characters. It is included in the response when you describe the instance. The client token is valid for at least 24 hours after the termination of the instance. You should not reuse a client token in another call later on.

If you repeat a request with the same client token, but change another request parameter, Amazon EC2 returns an `IdempotentParameterMismatch` error.

You can use the same client token for the same request across different regions. For example, if you send an idempotent request to launch an instance in the us-east-1 region, and then use the same client token in a request in other regions, we'll launch instances in each of those regions.

The following table shows common response codes and the recommended course of action.

<table>
<thead>
<tr>
<th>Code</th>
<th>Retry</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 (OK)</td>
<td>No effect</td>
<td>The request has succeeded and any further retries have no effect.</td>
</tr>
<tr>
<td>400 (Client Error)</td>
<td>Not recommended</td>
<td>The request will never succeed (for example, a specified parameter value is not valid). If the request involves a resource that is in the process of changing states, repeating the request could possibly succeed (for example, launching an instance using an Amazon EBS volume that is about to become available).</td>
</tr>
<tr>
<td>500 (Server Internal Error)</td>
<td>Recommended</td>
<td>The error is generally transient. Repeat the request with an appropriate back-off strategy.</td>
</tr>
<tr>
<td>503 (Server Unavailable)</td>
<td>Recommended</td>
<td>The error can occur when there is extreme load. Repeat the request with an appropriate back-off strategy.</td>
</tr>
</tbody>
</table>

**Idempotency Support**

The following commands and actions support idempotent operations using a client token:

- CopyImage
- CreateReservedInstancesListing
- `ec2-copy-image`
- `ec2-create-reserved-instances-listing`
- `ec2-modify-reserved-instances`
- `ec2-run-instances`
- ModifyReservedInstances
- RunInstances

The following commands and actions are idempotent.

- AssociateAddress
Example Idempotent Command

Use the `ec2-run-instances` command as follows to make an idempotent request:

```
PROMPT> ec2-run-instances ami-b232d0db -k my-key-pair --client-token 550e8400-e29b-41d4-a716-446655440000
```

The `--client-token` option requires a unique, case-sensitive string of up to 64 ASCII characters.

Example Idempotent Query

Use the `RunInstances` action as follows to make an idempotent request:

```
https://ec2.amazonaws.com/?Action=RunInstances
&ImageId=ami-3ac33653
&MaxCount=1
&MinCount=1
&KeyName=my-key-pair
&ClientToken=550e8400-e29b-41d4-a716-446655440000
&AUTHPARAMS
```

The `ClientToken` parameter requires a unique, case-sensitive string of up to 64 ASCII characters.

SOAP Requests

We have deprecated the SOAP API for Amazon EC2. We will continue to support SOAP requests for API versions up to and including version 2014-02-01, until the end of December 2014. If you use a SOAP request against a later API version, or after December 2014, you will receive the following response:

```
Client.UnsupportedProtocol: SOAP is no longer supported.
```

Similarly, the AWS software development kits (SDKs) will continue to support SOAP requests for Amazon EC2 API versions up to and including version 2014-02-01, until the end of December 2014.

We recommend that you use the Query API for Amazon EC2, or the SDKs for AWS. For more information, see Making API Requests (p. 664).
Document History
